Background: Primary malignant melanoma (PMM) of the bladder is extremely rare and has a poor prognosis; just 40 cases of PMM of the bladder have been recorded in the literature. We described a case of PMM of the bladder, treatment, and a review of the literature because the recommended treatment choices are not widely known.

Case Presentation: An 80-year-old Thai female came in with a three-month history of pelvic pain and dysuria without extensive hematuria. She underwent transurethral excision of the bladder tumor and histologically reported malignant melanoma with no further primary sites of melanoma after computed tomography indicated a big heterogeneous enhancing mass on the posterior wall of the bladder. The patient eventually underwent anterior pelvic exenteration with ileal conduit, but metastatic disease occurred one year later.

Conclusion: Bladder melanoma has a fatal aggressive nature. Certain diagnostic features can be obtained through histopathological investigation, immunohistochemistry, clinical history, and endoscopic evaluation. Despite a wide range of treatments, people with PMM still have a bad prognosis.

Keywords: primary malignant melanoma, rare bladder tumor, extracutaneous melanoma, radical cystectomy

Introduction

Primary malignant melanoma (PMM) of the bladder is extremely rare and has a poor prognosis; just 40 cases of PMM of the bladder have been recorded in the literature. We described a case of PMM of the bladder, treatment, and a review of the literature because the recommended treatment choices are not widely known.

Case Presentation

An 80-year-old Thai female was presented with pelvic pain and dysuria without gross hematuria for 3 months. After medical history and complete physical examination were obtained. CT abdomen was done and revealed a large heterogeneous enhancing mass 5.3×6.2 cm in size with internal calcification in the urinary bladder (Figure 1). Cystoscopy revealed a large necrotic mass that could not be identified as the ureteric orifice or the bladder base and a transurethral resection of the bladder tumor was performed. The pathological report revealed malignant melanoma spindle cell variant. Hematoxylin and eosin (H&E) staining was performed on tissue sections and S100 (+), HMB-45 (+), and Melan-A (+) were detected by immunohistochemistry (Figure 2). Complete investigations were performed to exclude other primary sites of melanoma. Dermatologic, otorhinolaryngologic, ophthalmologic

Figure 1 Axial (A) and sagittal (B) CT scans of the whole abdomen included the pelvis with IV contrast injection demonstrated a large heterogenous enhancing mass, 5.3×6.2 cm in size with internal calcification in the urinary bladder.

Figure 2 The histological appearance of the urinary bladder melanoma tissue was composed of solid nests and groups of atypical, poorly differentiated, highly mitotically active cells with prominent nucleoli: HE $\times 10$ (A); HE $\times 100$ (B); HE $\times 400$ (C); immunohistochemistry indicating positive reaction to HMB-45 ($\times 100$) (D); Melan-A ($\times 100$) (E) and S-100 ($\times 100$) (F).

and proctologic examinations were unremarkable, and upper gastrointestinal endoscopy and colonoscopy were performed and showed normal findings. Computed tomography (CT) scans of the abdomen, chest, brain and bone scans found no metastasis or other suspected primary lesions. Primary malignant melanoma of the bladder was diagnosed, and a multidisciplinary team approach

suggested no further adjuvant therapy was needed because of the patient's age, comorbidity and poor prognosis despite treatment. The patient agreed to take the risk and had an anterior pelvic exenteration with an ileal conduit performed. The pathology revealed malignant melanoma and invasion of the bladder serosa's posterior wall, but all resection margins of the pelvic lymph nodes were negative

for metastasis. After a postoperative period of one year, a computerized tomography scan showed new cardiophrenic lymph node enlargement without local recurrence (Figure 3). Tissue biopsy was performed and reported for metastasis malignant melanoma. The patient refused a metastasectomy and thus missed the follow-up.

Discussion and Conclusions

Primary malignant melanoma is very rare in the genitourinary tract, and extremely rare in the bladder. We reported a case of PMM of the bladder, with previously reported 39 cases worldwide as in Table 1. The most common presenting symptom is hematuria. The diagnosis of bladder malignant melanoma requires cystoscopy and tissue biopsy. Cystoscopy revealed a dark pigmented tumor.^{1,2} Melanoma-like features such as melanin pigment, nests of pleomorphic cells with macronuclei, and prominent nucleoli were observed during the pathologic examination. Typically, immunohistochemical evaluations demonstrate positivity for S-100, HMB-45, MART-1/Melan-A, Tyrosinase and MITF.⁷ A patient history and physical examination of the skin and were also evaluated for visceral primary sites to distinguish primary from secondary melanomas of the bladder comprehensively.⁵

In 1976, Ainsworth established the correct definition of bladder melanoma, including careful physical examination, including the skin with Wood's light, together with a detailed history to exclude cutaneous melanoma, pattern

of recurrence consistent with primary melanoma of the urinary bladder, histologically proved primary atypical melanocytes and also, especially, exclusion of visceral melanoma following complete evaluation.⁸ Malignant melanoma's histogenesis in the urinary tract, particularly in the bladder, is unknown. There are currently two theories: one supports the idea that melanoblasts migrate from the neural cusps into the mesenchyme during embryogenesis, but they can also migrate to ectopic places, such as the developing urinary tract, where they remain inactive for a long time before transforming into malignant cells under the influence of some local factors. Another theory is that urothelial cells produced from urothelial stem cells may develop into malignant melanocytes.⁴ Transurethral resection of a bladder tumor, partial or radical cystectomy, radiotherapy, chemotherapy and immunotherapy are the treatment options. However, initial treatment for organ-confined tumors involves surgery for both partial and radical cystectomy with lymph node resection. If there are contraindications for surgery, chemotherapy for systemic therapy is not proper, and radiotherapy and immunotherapy with interferon- α can be administered.

Overall, reports of the treatment outcomes of patients with this tumor are still poor, despite the variety of therapies available. Most patients die due to widespread metastases within 3 years after the initial diagnosis.^{5,9,10} This was the case for our patient, who was diagnosed at a localized stage and received anterior pelvic exenteration, but still developed a metastatic disease within 1 year after

Figure 3 Axial (A) and coronal (B) CT scan of the abdomen/pelvis with IV contrast injection, demonstrated a new left cardiophrenic lymph node enlargement.

treatment. According to a literature review, PMM of the bladder has a poor prognosis for many reasons, advanced stage as presenting symptom, difficult to diagnose by confirmed pathology and aggressiveness, with two-thirds of patients developing metastatic disease within three years.^{5,6} In addition, there is a lack of data suggesting the best treatment options. It appears that tumor stage and mitotic activity can help in prognosis and some authors suggest that identifying if the malignancy contains a BRAF-activating mutation for therapeutic targeting may be of benefit^{4,5} and previous report of BRAF mutations has shown in melanoma about 60% of cases.¹¹ Others have suggested immunotherapy after a radical cystectomy with nivolumab as a successful treatment.³

In conclusion, primary malignant melanoma of the bladder is a very rare disease. Complete investigation to distinguish primary from secondary disease is very important. The choice of treatments should be based on overall prognosis, the patient's factors and aggressiveness of disease. Despite the variety of therapies, the prognosis of patients with this tumor is still poor. However, local control with aggressive surgery has still shown benefits in survival.

Research and Reports in Urology

Publish your work in this journal

Research and Reports in Urology is an international, peer-reviewed, open access journal publishing original research, reports, editorials, reviews and commentaries on all aspects of adult and pediatric urology in the clinic and laboratory including the following topics: Pathology, pathophysiology of urological disease; Investigation and

treatment of urological disease; Pharmacology of drugs used for the treatment of urological disease. The manuscript management system is completely online and includes a very quick and fair peer-review system, which is all easy to use. Visit <http://www.dovepress.com/testimonials.php> to read real quotes from published authors.

Submit your manuscript here: <https://www.dovepress.com/research-and-reports-in-urology-journal>
