Background: Despite the availability of synthetic antihyperglycaemic medications on the market, diabetes is on the rise. Though not scientifically proven, the *Crinum abyssinicum* Hochst. ex A. Rich. (Amaryllidaceae) has been used traditionally to treat diabetes. *Crinum abyssinicum* was tested in mice to see if it had anti-diabetic and anti-hyperlipidemic properties.

Methods: The hydro-alcoholic extract of *Crinum abyssinicum* shoot tips doses (100 mg/kg, 200 mg/kg, and 400 mg/kg) were administered to normoglycemic, oral glucose-loaded mice, and single and repeated dose-treated streptozotocin-induced diabetic model. Then, the blood glucose levels were measured for normoglycemic, oral glucose loaded and single dose treated streptozotocin model. Whereas in repeated dose-treated streptozotocin induced diabetic model, blood glucose level, body weight, and lipid profiles were measured.

Results: After oral administration, all extract doses (100 mg/kg ($p < 0.01$), 200 mg/kg ($p < 0.001$), and 400 mg/kg ($p < 0.001$)) significantly reduced blood glucose level of normal mice as compared to the control group. Significant reduction of post-prandial glucose was achieved with crude extract at a tested dose of 100 mg/kg ($p < 0.05$) both at 1st and 2nd hours; 200 mg/kg ($p < 0.01$) at the 1st hour and ($p < 0.001$) 2nd hours, and 400 mg/kg ($p < 0.001$) at the 1st and 2nd hours as compared to the negative control. In diabetic mice, the crude extract 200 mg/kg and 400 mg/kg; and glibenclamide 5 mg/kg significantly reduced ($p < 0.001$) blood glucose level on the 14th day as compared to the negative control. All doses of crude extract significantly improved the lipid profiles and the bodyweight of diabetic mice.

Conclusion: These findings revealed that the hydro-alcoholic extract of *Crinum abyssinicum* shoot tips possess significant anti-hyperglycemic, antihyperlipidemic, and body weight improvements in streptozotocin-induced diabetic mice. Besides, it showed hypoglycaemic and anti-hyperglycaemic activities on normoglycemic and oral glucose loaded mice, respectively. These justify the claimed use of the plant in ameliorating diabetes mellitus in Ethiopian folk medicine.

Keywords: antidiabetic, antihyperlipidemic, *Crinum abyssinicum*, hydro-alcoholic, streptozotocin

Background

Diabetes Mellitus (DM) is a metabolic condition that is chronic and non-communicable.¹ It is a growing global health problem that is viewed as an “iceberg” hormonal disease defined by a loss of control over blood glucose levels as a result of carbohydrate, lipid, and protein metabolic dysfunctions. In about one-third to one-half of patients with diabetes, micro-vascular (retinopathy, nephropathy, and neuropathy) and macro-vascular (ischemic heart disease, peripheral vascular disease, and cerebrovascular disease) problems are tightly linked.² Uncontrolled hyperglycemia can cause consequences such as increased lipid peroxidation, superoxide generation, lipoprotein glycation, and oxidative DNA damage through tissue protein glycation. Reactive species such as hydrogen peroxides (H₂O₂) and hydroxyl radicals are produced as

a result of glycation and glucose auto-oxidation (OH⁻). As a result, it has a global impact on human life in one or more ways.^{3–5}

DM is common worldwide, and its incidence is on the rise, with disproportionately higher rates in low- and middle-income countries (LMICs), and its fatality rate is steadily rising. According to a World Health Organization (WHO) report from 2019, a little under half a billion people worldwide have diabetes, with the number expected to rise by 25% in 2030 and 51% in 2045.^{6,7} Diabetes has become a major health issue in Ethiopia, as it has throughout the world. With a prevalence of diabetes, pre-diabetes, and previously undiagnosed diabetes of 6.8%, 15.7%, and 72.5%, respectively. Ethiopia is among the top four nations in sub-Saharan Africa with the largest number of persons with diabetes and hospital admissions owing to diabetes.^{7,8}

Despite the introduction of various types of traditional oral hypoglycaemic medications on the market, diabetic prevalence and health-care spending are rising at an alarming rate around the world. Diabetes is expected to cost the world economy USD 760 billion, USD 825 billion, and USD 845 billion in 2019, 2030, and 2045, respectively.⁹ As a result, these issues necessitate the development of new anti-diabetic drugs derived from natural sources, particularly plants, that are safe, readily available, more efficacious, have a novel mode of action, broad therapeutic potential, and are structurally distinct from currently available drugs.^{10,11}

Herbal medicines are encouraged, recommended, and promoted by WHO in national health care programs because they are inexpensive, reasonably safe, and have a high level of trust among the people.

Because of their bioactive phytochemical contents (nitrogen-containing alkaloids, phenols, flavonoids, saponins, tannins, and other compounds), medicinal plants offer antioxidation, anti-inflammatory, and anti-diabetic properties.^{2,12–14} These phytochemical ingredients have anti-hyperglycaemic properties through restoring pancreatic tissue function, resulting in an increase in insulin secretion, or by inhibiting glucose absorption in the intestine or facilitating metabolite transport in insulin-dependent processes.^{15,16} Furthermore, natural antioxidants may help with diabetes management by offering protection against free radical damage. Natural products, on the other hand, have received a lot of attention as sources of bioactive substances like antioxidants, hypoglycaemic, and anti-hyperlipidaemia by lowering plasma insulin and Glycated haemoglobin (HbA1c) levels. Maintaining a lipid profile is vital to lower the risk of coronary heart disease and atherosclerosis caused by diabetes, as it may occur from diabetic dyslipidaemia (hyperlipidaemia). In comparison to non-diabetics (normal mice), raised serum Triglycerides (TGs), Very Low-Density Lipoprotein (VLDL), high small dense Low-Density Lipoproteins (LDL), and low serum High-Density Lipoprotein-Cholesterols (HDL-C) levels are connected with the most prevalent problem in diabetes patients.^{2,5}

Enzyme inhibitory theory is regarded as one of the most effective therapeutic approaches for addressing global health issues such as DM. As a result, lipolysis blockade has emerged as a unique method for the treatment of obesity and its comorbidities. Many plants contain arginine-containing tri-peptides (Pro-Arg-Gly), which are thought to be effective phospholipase inhibitors and involved in the regulation of anticoagulation and insular systems function under persistent hyperglycemia.^{17,18} In diabetic rats, the nutraceutical potential of *Corylus avellana* daily supplement for obesity and dysmetabolism¹⁹ and *Juglans regia* L. leaf powder was investigated, and effective glycaemic control and dyslipidemias reversal were seen.²⁰

The Amaryllidaceae family, which includes 79 genera, is a highly ubiquitous monocotyledonous family found in all biomes around the world.²¹ *Crinum* is one of the therapeutic plants in this family, which includes several species with bulbous geophytes and grows in places with a lot of seasonality.²² Lycorine, epihalmanthidine, crinafolidine, crinasiatine, precirwelline, crimine, narciclasine, crinamine, crinamide, lycobetaine, criasbetaine, crinasiadine, and crotepoide are among the phytochemical chemicals found in it. Plant extracts rich in lycorine and other alkaloids have anti-oxidant, anti-inflammatory, cytotoxic, immune-stimulating, analgesic, antiviral, antimalarial, antimicrobial, and anti-diabetic properties, as well as anti-diabetic properties.^{23,24} Different solvent extracts have been generated from the leaves and bulbs of *Crinum* species in numerous biological experiments due to their significant phytochemical ingredients with vast pharmacological activity.²⁵ Plants in this family, such as *Allium sativum* (garlic) and *Allium cepa* (onion), have shown strong antioxidant and hypoglycaemic activities in pharmacological studies.²¹ Furthermore, ethanol and aqueous extracts of *Crinum latifolium* Linn's leaves demonstrated considerable anti-diabetic potential.²⁶ *Crinum jagus* aqueous and hydro-alcoholic extracts have anti-oxidant and anti-diabetic effects in vitro and in vivo, respectively.²⁷ This suggests that,

like the aforementioned plants, the study plant may have anti-oxidant and anti-diabetic properties. The existence of considerable bioactive elements (alkaloids, flavonoids, saponins, tannins, and phenols) was confirmed in a prior qualitative and quantitative phytochemical examination on the bulbs of *Crinum abyssinicum*²⁸ that is already recognized to have anti-oxidant and blood glucose reducing properties. In Ethiopia, an ethno-medicinal survey and qualitative exploratory research revealed that the herb is consumed orally for the treatment of diabetes mellitus.^{23,29–31}

Crinum abyssinicum Hochst. ex A. Rich. is locally known as “yejib shinkurt” in Amharic³² and “Murquffaa”/ Shinkurta/boko lo werabessa in Afaan Oromoo.^{23,33} It has been found in Ethiopia’s most floristic regions as well as Eritrea, but it is unknown outside of the Horn of Africa.³⁴ In Ethiopia, different components of *Crinum abyssinicum* are traditionally used to treat a variety of diseases other than diabetes, including as wounds, canceroids, hypertension, diabetes, haemorrhage, hepatitis B, skin infection, and several types of tumors;^{23,33,35} roots for hepatitis-B and hemorrhage;³³ leaves for skin infection and swelling and cancer (tumor);³⁶ roots and bulbs for snakebite³⁷ and earache;³⁸ bulbs for rheumatoid;³⁸ an evil spirit.³²

Despite Ethiopian traditional medicine’s usage of this medicinal plant to treat diabetes and the aforementioned condition, no scientific study has been conducted. As a result, the goal of this study is to see if the traditional usage of *Crinum abyssinicum* shoot tips to treat diabetes has any scientific backing.

Methods

Drugs and Chemicals

The following drugs, chemical supplies, and instruments were utilized; Streptozotocin (Fisco Research laboratories), glibenclamide (Julphar Pharmaceuticals, Ras Al Khaimah, UAE), citric acid monohydrate (Lab Tech Chemicals, Mumbai, India), trisodium citrate dihydrate (Blulux Laboratories, Faridabad, India), ethanol absolute (Nice chemical, India), halothane (Primal Enterprises, India), 40% glucose solution (Reyoung Pharmaceuticals, Shandong, China), distilled water, hydrochloric acid and ferric chloride (BDH Laboratory Supplies Poole, England), acetic anhydride and Mayer’s reagent (May and Baker LTD Dagenham, England), and sulfuric acid (Fisher Scientific, UK), sodium hydroxide (BDH, chemical lab, England).

Collection and Preparation of the Extract

Crinum abyssinicum fresh shoot tips were obtained in the Sinan district of Ethiopia’s East Gojjam Zone, near Debre Markos. During shipment, the plant material was wrapped in plastic sheets and authenticated by Mr. Abiyu Enyew, a botanist at the University of Gondar’s Biology Department. With voucher number 001BAT/2019, a voucher specimen was deposited in the herbarium of the University of Gondar’s Department of Biology for future reference. The plant shoot tips were cleansed with tap water after collecting and air-dried at room temperature in the shade with enough ventilation. After that, the size was reduced to a reasonably coarse powder using a mortar and pestle. A sensitive digital weighing balance was used to weigh the powdered plant ingredients. The extraction was carried out in an Erlenmeyer flask for 3 days at room temperature using 6 liters of hydro-alcoholic for 575 g of moderately powdered shoot tips (10:1 v/w) solvent to dry weight ratio.³⁹ The extraction process was aided by periodic shaking, and the extract was subsequently filtered using muslin cloth and Whatman filter paper No.1 The residue was re-macerated for 3 days by repeating the process three times with the same volume of solvent to completely extract the plant material, and the filtrates were dried in a hot air oven at a temperature of not more than 40°C. The dried shoot tips extract was then preserved in a desiccator until it was needed.

Experimental Animals

Swiss albino mice were used, which were bred at the University of Gondar’s School of Pharmacy, College of Medicine and Health Sciences’ animal house facilities. Because male mice are more compatible and sensitive than female mice, the researchers utilized healthy male mice weighing 25–35 grams (8–12 weeks) in the investigation. According to a recent study, female mice with a body weight of 25–35 grams (8–12 weeks) were recommended for acute oral toxicity testing.^{40,41} The mice were kept in a regular environment (six mice per polypropylene cage) with a 12-hour light/12-

hour dark cycle and unlimited access to standard pellets and water. Throughout the experiment, they were cared for and managed according to the international criteria for the use and maintenance of experimental animals provided by the Organization for Economic Cooperation and Development (OECD) and the Institute for Laboratory Animal Research (ILAR). The mice were randomized at room temperature and given one week to acclimate to the laboratory surroundings before beginning the treatments. Mice were sacrificed painlessly and humanely via cervical dislocation at the end of each experiment, and then buried in the college's disposal area.^{42,43}

Preliminary Phytochemical Screening Tests of Crude Extracts of *Crinum abyssinicum*

The crude extract of *Crinum abyssinicum* shoot tips was subjected to qualitative tests for identification of different phytochemical constituents (secondary metabolites) such as alkaloids, phenolic compounds, glycosides, cardiac glycosides, flavonoids, saponins, tannins, steroidal compounds, terpenoids, and anthraquinones using standard chemicals used for qualitative preliminary phytochemical screening tests with minor modifications.⁴⁴

Acute Oral Toxicity Test

Before beginning the entire study, a preliminary acute oral toxicity test was done on the crude extract, following the limit test instructions of the Organization for Economic Cooperation and Development (OECD) No 425 Guideline to rule out any signs of toxicity. Five female albino mice (one animal step wisely) were chosen at random after a week of acclimating. Initially, a single healthy female mouse was fasted for 4 hours (except, water). The extract was subsequently given orally at a dose of 2000 mg/kg. Following that, it was closely monitored for 24 hours for any physical or behavioral changes, with special care paid for in the first 4 hours following administration. The remaining four healthy female mice were chosen based on the results of the first mouse.

Grouping and Dosing of Animals

To depict the variability exhibited in human diabetic patients, it is advantageous to employ more than one animal model. As a result, four distinct diabetes models were used: normoglycemic, oral glucose loaded, single and repeated dosage STZ-induced diabetic models. Mice were randomly allocated to five groups in the normoglycemic and oral glucose loading scenarios (6 mice per group). Group I (negative control) received 10 mL/kg distilled water (DW); Group II (positive control) received the standard medicine glibenclamide (GLC5mg/kg); and Groups III–V (test groups) received *Crinum abyssinicum* crude extract at concentrations of 100 mg/kg, 200 mg/kg, and 400 mg/kg, respectively. The dose values were determined using the OECD 425 acute oral toxicity data.⁴⁵

There were five different diabetic test groups (groups I–V) in a single-dose STZ induced diabetic animal model: diabetic negative control group (group I) was treated with vehicle (DW); diabetic positive control group (group III–V) was treated with standard drug (GLC5 mg/kg); and diabetic positive control group (group III) was treated with different doses of *Crinum abyssinicum* crude extract (100 mg/kg, 200 mg/kg, and 400 mg/kg CACE). The goal of this model is to determine the link between the crude extract's blood glucose reducing actions and the passage of time.

Mice were randomly assigned into six groups in the repeated-dose STZ produced diabetic paradigm (five groups of diabetic mice and one additional group of normal mice) (six mice per group). Group I (diabetes negative control) received 10 mL/kg DW; Group II (diabetic positive control) received GCL 5 mg/kg; and Groups III–V (diabetic test groups) received various doses of *Crinum abyssinicum* crude extract (100 mg/kg, 200 mg/kg, and 400 mg/kg CACE). 10 mL/kg DW was given to Group VI (normal negative control). This model was created to investigate the extract's long-term effects on body weight and lipid profiles in a time-dependent manner.

The hypoglycemic drug glibenclamide was chosen as a reference drug because sulfonylureas are known to stimulate insulin secretion from existing pancreatic beta cells in the streptozotocin (STZ) diabetic rodent model and to compare the efficacy of a variety of glucose-lowering compounds via increased activity of pancreatic β -cells, resulting in the secretion of larger amounts of insulin.^{46–49} The study was conducted utilizing the oral method of administration since, as previously stated, people generally utilize orally. The following calculation was used to compute the percentage reduction in BGL:

$$(\%) \text{ reduction in BGL} = \frac{\text{BGL at baseline} - \text{BGL on 14}^{\text{th}} \text{ day}}{\text{BGL at baseline}} * 100$$

Measurement of Blood Glucose Level

Blood samples were withdrawn aseptically by snipping the tip of the tail in all animal models to assess the blood glucose level (BGL). BGL was tested with a glucometer in triplicates, with the average value being used.⁵⁰

The Effect of Crude Extract on Normoglycemic Mice

Healthy normal mice were fasted for 14 hours, with water available ad libitum. After that, they were divided into five groups at random (six mice per group). Mice were grouped and treated as previously reported. All mice's BGL was assessed before treatment (at t=0 hours as a baseline), then at 1, 2, 4, and 6 h after treatment.⁵¹

The Effect of Crude Extract on Oral Glucose Tolerance Tests

Healthy normal mice were fasted for 14 hours, with water available ad libitum. After that, they were divided into five groups at random (six mice per group). Each mouse was given a 2000 mg/kg body weight glucose solution orally 30 minutes before the extract was given. They were then administered extract doses orally in accordance with their different groups. Each animal's BGL was tested before treatment (at t = 0 h as a baseline), then at 0.5, 1, and 2 h after glucose injection.⁵²

Induction of Experimental Diabetes

STZ, dissolved in a 0.1 M cold citrate buffer (pH = 4.5), was used to induce diabetes. To identify the proper dose range, pretests were performed at 60 mg/kg, 90 mg/kg, and 150 mg/kg body weight. A single dosage of 150 mg/kg freshly produced solution was administered intra-peritoneally to overnight fasted mice depending on the results of the pretest (for 14 hours). Animals were given free access to food and water thirty minutes after being given STZ. After 6 hours of STZ administration, the animals were given a 5% glucose solution for the next 24 hours to prevent hypoglycemia shock caused by hyper-insulinemia. After three days of induction, the animals were tested for diabetes. The mice with a fasting BGL of more than 200 mg/dl were then included in the research. STZ-induced diabetic rats were randomly assigned to separate groups to experiment immediately after the screening. To reduce wetness caused by polyuric diabetic mice, the cage bedding was replaced daily.^{47,53}

Effect of Single Dose of Crude Extract on Streptozotocin-Induced Diabetic Mice

After overnight fasting (for 14 hours), STZ-induced diabetic mice were assigned randomly into five different groups (six diabetic mice per group) then mice were treated with vehicle, standard drug, and crude extract of *Crinum abyssinicum* according to their respective groups as already described above. BGL was measured just before treatment (at 0 h) as a baseline, and then at 2, 4, 6, and 8 h post-treatment.⁵⁴

Effect of Repeated Dose Crude Extract on Streptozotocin-Induced Diabetic Mice

After successfully developing STZ-induced diabetes, the experimental animals were divided into six groups (six mice per group). The vehicle, standard drug, and crude extract were administered once daily for 14 days as the protocol described above. The fast BGL and body weights were measured just before treatment (day 0), 7th, and 14th day.^{55,56}

Effects of Crude Extract on Serum Lipid Level of Diabetic Mice

On the 15th day, a blood sample was taken from overnight fasted (for 14 hours) diabetic mice using a sterile tube after cardiac puncturing under halothane anaesthesia.⁵⁷ The blood samples were left at room temperature for 2 hours before being centrifuged for 15 minutes at 2500 rpm at 30°C. The supernatant was removed from the pellet immediately to create serum samples for automated chemistry analyzer analysis of serum triglyceride (STG), serum total cholesterol (STC), high-density lipoprotein (HDL), and low-density lipoprotein (LDL).

Statistical Analysis

All statistical analyses were carried out with SPSS version 23 statistical program for social science. For six mice in each group, the data were reported as mean $\pm$ standard error of the mean (S.E.M). One-way analysis of variance (ANOVA) was used to compare the means of all parameters across groups and within groups, followed by Tukey's post hoc multiple comparison tests. Statistical significance was defined as a *P*-value of less than 0.05.

Results

Yields

The extraction of 575 grams of *Crinum abyssinicum* shoot tips yielded 105 grams of crude extract. The percentage yield of *Crinum abyssinicum* shoot tips hydro-alcoholic crude extract was reported to be 18.26% (w/w).

Acute Oral Toxicity Tests

Within the first 24 hours and up to 14 days of observation, a 2000 mg/kg dose of hydro-alcoholic crude extracts of *Crinum abyssinicum* shoot tips did not show any signs of toxicity such as restlessness, motor activity, respiration, or diarrhea. To put it another way, all mice survived for the first 24 hours and up to 14 days in the cage. As a result, the median lethal dose (LD50) of the extract required to kill 50% of the animals is larger than 2000 mg/kg, implying a good safety margin.

Preliminary Phytochemical Screening Tests

Preliminary phytochemical analysis was performed on crude extracts of *Crinum abyssinicum* shoot tips using color generating and precipitating chemical reagents, which verified the existence of phytochemical elements (Table 1).

Effect of Crude Extract on Normoglycemic Mice

Table 2 shows the findings of hydro-alcoholic crude extracts of *Crinum abyssinicum* shoot tips in normoglycemic mice. During the first hour after administration, there were no statistically significant variations in BGL among the treatment groups. CACE 100 mg/kg had no effect on blood sugar levels. When compared to mice receiving DW10ml/kg, the other doses showed a substantial reduction commencing at different time points: 2nd h ($p < 0.01$) for 400 mg/kg and 4th h ($p < 0.01$) for 200 mg/kg; 6th h ($p < 0.001$) for both 200 mg/kg and 400 mg/kg. At these time points, the hypoglycemia induced was much lower than the standard ($p < 0.01$). Treatment with GLC 5mg/kg lowered BGL considerably ($p < 0.001$), with percentage reductions of 10.28% at the 2nd h, 33.87% at the 4th h, and 44.96% at the 6th h compared to baselines (fasting BGL). CACE 200 mg/kg resulted in significant BGL reductions ($p < 0.01$) and ($p < 0.001$) during the 4th and 6th hours, with percentage reductions of 12.57% and 15.57%, respectively. CACE 400 mg/kg, on the other hand, demonstrated a significant BGL reduction ($p < 0.01$) with a percentage decrease of 9.79% at the 2nd h and ($p < 0.001$) with percentage reductions of 27.19 and 38.40% at the 4th and 6th h, respectively.

Effect of Crude Extract on Oral Glucose Loaded Mice

Table 3 shows the effects of *Crinum abyssinicum* shoot tips crude extract on Oral Glucose Loaded Non-Diabetic Mice. The BGL reached its maximum level at 0.5 h after an oral glucose challenge with a dose of 2000 mg/kg in non-diabetic mice. The BGL was significantly lowered with the tested doses of 100 mg/kg ($p < 0.05$) at the 1st and 2nd h, 200 mg/kg ($p < 0.01$) and ($p < 0.001$) at the 1st and 2nd h, respectively. However, as compared to the negative control, the tested dose of 400 mg/kg and the GLC 5mg/kg resulted in a substantial improvement in BGL ($p < 0.001$) at both the 1st and 2nd h. Intra-group analysis, on the other hand, revealed that oral glucose loading results in a statistically significant drop in BGL at the 1st and 2nd hour.

Effect of Single Dose Crude Extract on Streptozotocin-Induction of Diabetes

In this study, seventy-six mice were given a 150 mg/kg dosage of STZ intra-peritoneal injection and were determined to be diabetic (fasting BGL > 200 mg/dl) 3 days after the injection, with a success rate of 72.37%. Six mice died before the extract was administered, while the others lived to see the end of the trial. Table 4 shows the results of the anti-

hyperglycemic impact of *Crinum abyssinicum* hydro-alcoholic crude extract on STZ-induced diabetes. When groups receiving the plant extract were compared, there was no statistically significant variability between baselines (fasting BGL) across all groups and at all-time points. In all doses of crude extract, the intra-group analysis revealed no statistically significant BGL reduction. Nonetheless, when compared to the corresponding fasting BGL, the percentage reduction in BGL was determined to be 11.22% with CACE 400 mg/kg and 17.24% with GLC 5mg/kg treated group at the 8th hour. When compared to the negative control, GLC 5 mg/kg resulted in statistically significant BGL reductions

(p < 0.01) at the 4th, (p < 0.001) at the 6th, and (p < 0.001) at the 8th h. Similarly, as compared to the negative control, CACE 400 mg/kg demonstrated statistically significant BGL reduction (p < 0.01) at the 6th hour and (p < 0.001) at the 8th hour. When compared to baseline, GLC 5 mg/kg resulted in a substantial blood glucose reduction (p < 0.05) at the 4th and 6th hour, and (p < 0.01) at the 8th hour (fasting BGL).

Effect of Repeated Doses of Crude Extract on STZ-Induction of Diabetic Mice

The BGL of normal and diabetic mice was tested once a week after treatment with CACE, DW10, and GLC5. Table 5 summarizes their findings. Diabetic mice demonstrated significant variations in BGL (p < 0.001) throughout all time intervals after induction compared to non-diabetic (normal) mice, but no significant differences in baselines (fasting BGL) across all diabetic mouse groups. On the 7th day, treatment doses of CACE100 mg/kg (p < 0.05) and CACE 200 mg/kg (p < 0.01) produced in statistically significant reductions in baselines (fasting BGL) when compared to diabetes control. Similarly, as compared to diabetic control, CACE 400 mg/kg and GLC 5 mg/kg result in a substantial reduction in BGL (p < 0.001) on the 7th day. Similarly, as compared to diabetes negative control, CACE 100 mg/kg (P < 0.01) and all other treatment groups (CACE 200 mg/kg, CACE 400 mg/kg, and GLC5 mg/kg) cause substantial reductions in baselines (fasting BGL) on the 14th day (p < 0.001). On the 14th day, CACE 100 mg/kg (6.6%), CAE 200 mg/kg (13.26%), CACE 400 mg/kg (23.51%), and GLC 5 mg/kg (37.16%) showed the greatest percentage reduction in fasting BGLs. CACE 400 mg/kg significantly reduced BGL (p < 0.05 and p < 0.001) on the 7th and 14th days, respectively, when compared to the baseline (fasting BGL) level, according to the intra-group analysis. On the 7th and

14th days, however, neither the diabetes negative control group nor the normal control group showed a significant drop in BGL relative to their respective baseline (fasting BGL) levels.

Effect of the Repeated Daily Doses of Crude Extract on Body Weight of Diabetic Mice

The body weight of mice was evaluated 72 hours after STZ injection before extract delivery, and there was no significant difference between diabetic groups, but there was a considerable weight loss when compared to the normal control group. There was no discernible difference in bodyweight between the treatment groups and the usual control group. At the 7th and 14th days of treatment, STZ induced a considerable reduction of body weight in diabetic control compared to normal control (Table 6). On the 7th day of treatment, a statistically significant body weight gain was found with CACE 200 mg/kg ($p < 0.001$), and GL5 mg/kg ($p < 0.001$) as compared to the diabetes control group. CACE 100 mg/kg also caused a substantial increase in body weight ($p < 0.01$). When compared to diabetes control, all other doses of crude extract (CACE 200mg/kg), CACE 400 mg/kg, and the reference medicine (GLC5 mg/kg) showed a substantial ($p < 0.001$) increase in body weight after 14 days. On the other hand, when compared to the normal control group, the diabetes control group's body weight was considerably lower ($p < 0.05$ and $p < 0.001$) on the 7th and 14th days. The intra-group analysis revealed that on the 7th and 14th days of treatment, the CACE 400 mg/kg and GL5 mg/kg showed a substantial

increase in body weight when compared to baseline body weight. CAC 200 mg/kg, on the other hand, exhibited a substantial increase in body weight on the 14th day when compared to baseline.

Effect of Repeated Daily Doses of Crude Extract on Lipid Profile of Diabetic Mice

Table 7 summarizes the effect of crude extract on lipid profiles. When compared to non-diabetic (normal) mice, there was a substantial increase ($p < 0.001$) in STC, STG, and LDL cholesterol content and a significant decrease ($p < 0.001$) in HDL cholesterol content after diabetes induction. On the other hand, when all dosages of crude extract (CACE100mg/kg, CACE 200 mg/kg, CACE 400mg/kg, and GLC 5mg/kg) were given orally for 14 days, the contents of STC level decreased significantly ($p < 0.001$) when compared to diabetes negative controls in a dose-dependent manner. At the end of the treatment period, the amounts of STG were considerably reduced ($p < 0.05$) with CACE 100 mg/kg and ($p < 0.001$) with CACE 200 mg/kg, CACE 400 mg/kg, and GLC 5mg/kg when compared to diabetes control. In comparison to diabetic controls, HDL content was significantly raised with tested dosages of CACE 200 mg/kg ($p < 0.01$), CACE 400 mg/kg ($p < 0.001$), and GLC 5 mg/kg after 14 days of treatment. LDL cholesterol content, on the other hand, was considerably reduced in a dose-dependent manner with CACE 100 mg/kg ($p < 0.01$) and CACE 200 mg/kg, CACE 400 mg/kg ($p < 0.001$).

Discussion

Glycuria, hyperglycemia, polyphagia, polydipsia, and body weight loss are all observed in STZ-induced diabetic mouse models. Because this parallels human diabetes, in vivo anti-diabetic effects in mice are usually studied.⁵⁸

In an acute oral toxicity investigation, giving mice a single dose of 2000 mg/kg of hydro-alcoholic crude extract did not result in any toxicity or mortality under observation. As a result, this study demonstrated that the plant extract's LD50 is larger than 2000 mg/kg, which is consistent with Hussein's 2019 finding that an 80% methanol extract of *Crinum abyssinicum* bulbs was non-toxic.⁵⁹

DW10ml/kg had no effect on the blood glucose concentrations of overnight fasted normoglycemic mice on the hypoglycemic activity of the crude extract of *Crinum abyssinicum* shoot tips. After the second hour of post-treatment, CACE 400 mg/kg shoot tips extract dosages began to have a substantial hypoglycemic impact in normal fasting mice. Normal mice's BGL was considerably reduced with extract doses of CACE 200 mg/kg ($p < 0.01$) at the 4th hour and ($p < 0.001$) at the 6th hour, as well as CACE 400 mg/kg ($p < 0.01$) at the 2nd hour and ($p < 0.001$) at the 4th and 6th hours in a dose-dependent manner. Both CACE 200 mg/kg and CACE 400 mg/kg extract doses generated substantial hypoglycemic action, which was comparable to GLC 5mg/kg at the 6th hour, with a slightly greater significance level detected in the reference medication (GLC 5mg/kg). This could indicate that the extract's active phytochemical ingredients need time to reach a sufficient concentration at the site of action. In normal experimental animals, glibenclamide produces

hypoglycemia by stimulating insulin release from pancreatic β -cells and inhibiting glucagon secretion. Flavonoids, terpenoids, alkaloids, saponins, and tannins are phytochemical elements (secondary metabolites) that have been proven to exhibit hypoglycemic activity via an insulin-like effect or to induce insulin production from pancreatic beta-cells.⁶⁰ It is possible that the hypoglycemic impact of the hydro-alcoholic extracts of *Crinum abyssinicum* shoot tips is due to the presence of one or more of these bioactive components. This suggests that the plant extract's likely mechanism of action is comparable to that of the reference medicine.

The Oral Glucose Tolerance Test (OGTT) is the gold standard for determining the body's glucose tolerance. Because it has a higher sensitivity than fasting plasma glucose, it is the primary diagnostic technique. As a result, it is a commonly recommended test for determining glucose homeostasis. It is particularly useful in instances of diabetes where the fasting BGL is only mildly high, as it is a well-accepted and commonly used assay to examine anti-hyperglycemic activity of numerous medicines and to determine the change in carbohydrate metabolism during post-glucose delivery.^{61,62} It also aids in the diagnosis of diabetes and poor glucose homeostasis by accurately measuring insulin sensitivity, insulin secretion, and cell activity. The OGTT model was utilized to examine this changed carbohydrate metabolism after glucose delivery.⁶² An increase in blood glucose promotes insulin production and, in turn, peripheral glucose consumption. Insulin can drive the increased BGL down to a normal level of in two to three hours, according to physiology.⁶³ The BGL reached its maximum level after 0.5 hours after all groups were given 2000 mg/kg body weight of glucose orally. This determines whether oral glucose loading causes physiologic hyperglycemia. By 0 minutes, there was no statistically significant difference in BGL between the groups, but at 0.5 hours, there was a statistically significant difference in BGL between the groups. Furthermore, the statistical analysis revealed a substantial difference between the groups at the first hour. At the 1st hour, multiple-comparison post-hoc testing demonstrated that GLC5 mg/kg resulted in a substantial ($p < 0.001$) drop in plasma sugar levels when compared to the negative control. Furthermore, multiple comparison post-hoc analyses revealed that during the 2nd hour, GLC 5mg/kg, CACE 200 mg/kg, and CACE 400 mg/kg showed a substantial ($p < 0.001$) reduction in BGL compared to the glucose-loaded control group. When compared to the blood glucose level at 0.5 hours, glucose tolerance was considerably improved ($p < 0.001$) in GLC 5mg/kg and all doses of the crude extract-treated groups starting from the second hour onwards. Mice given crude extract had a higher capability for glucose consumption. A previous study by Al-Ishaq, et al, 2019 reported that the mechanism to reduce postprandial hyperglycemia is by inhibiting carbohydrate hydrolyzing enzymes α -amylase, and α -glycosidase in the digestive system, thereby preventing postprandial hyperglycemia.

The presence of phytochemicals (secondary metabolites) such as flavonoids may further contribute to *Crinum abyssinicum*'s anti-hyperglycaemic action on the OGTT. Flavonoids have a number of essential metabolic health advantages, including diabetes, obesity, cardiovascular disease, and cancer. They slow the progression of diabetes and its complications by regulating glucose metabolism, hepatic enzyme activity, and lipid profile, inhibiting α -amylase and α -glycosidase, regenerating pancreatic β -cells, increasing peripheral glucose utilization, and blocking glucose transporter activity from the intestine.^{64,65} This research demonstrates that the claimed medicinal plant exhibits anti-hyperglycemic and glucose-lowering properties similar to glibenclamide, a drug that secretes insulin from pancreatic β -cells in T₂DM patients.

A substantial reduction in fasting BGL of all diabetic mice fed with hydro-alcoholic extract of *Crinum abyssinicum* and reference medication was seen when compared to diabetic control after a single dose of STZ-generated diabetes model. It is exciting to see that CACE 400 mg/kg reduced hyperglycemia caused by STZ by 11.22% after 8 hours after oral delivery. This study was almost identical to a prior publication in which *Hagina abyssinica* reduced BGL by 13.38% as reported by Kiflie et al, 2020.⁶⁶ The anti-diabetic activity correlates to GLC 5mg/kg, as shown in Table 4, and all dosages of the crude showed a dose-dependent reduction in blood glucose levels after oral administration. This could be due to the existence of significant concentrations of key phytochemical constituents(s) in the higher dose 400 mg/kg of plant extracts, as opposed to the lower 100 mg/kg and medium 200 mg/kg dose levels.

The greatest reduction of fasting blood glucose was reported with CACE 400 (23.51%) on the 14th day in the anti-hyperglycemic action of repeated daily doses of CACE in STZ-induced diabetic mice (Table 5). The outcome was comparable to the reference drug's result, which reduced fasting BGL by 37.16% on the same day. This study was substantially identical to a recent report by Kiflie et al, 2020, in which crude extract (20.68%) and GLC5 (35.93%) were

shown to be the most effective in lowering BGL.⁶⁶ Even though CACE 200 mg/kg and CACE 400 mg/kg showed substantial blood glucose reductions ($p < 0.001$) when compared to diabetes control on the 14th day (9.12% and 13.26%, respectively), the extract had a dose-dependent effect, which could be because the greater dose is more likely to have a higher concentration of the bio-active ingredients that are responsible for decreasing fasting BGL than the smaller dose. GLC 5mg/kg pulls down fasting BGL as a result of plasma membrane depolarization, which is caused by selective blockage of adenosine triphosphate (ATP) sensitive K⁺(KATP) channels, activating voltage-gated Ca²⁺ channels, cytosolic (Ca²⁺), and endogenous insulin secretion from pancreatic β -cells.⁶⁷ This could indicate that STZ at a dose of 150 mg/kg intra-peritoneal was insufficient to destroy whole-cells and/or that only a few cells survived to regenerate and release insulin. STZ uptake into pancreatic β -cells islets causes toxicity through a variety of mechanisms, including nitric oxide (NO) donation and free radical formation, resulting in a significant reduction in the intracellular insulin concentration of these cells.⁶⁸ Due to their antioxidant properties, different plant extract phytochemical constituent(s) have exhibited pancreas β -cell protecting action. The extract of *Crinum abyssinicum* was found to have similar antioxidant activity and a cell-protective impact in this investigation. In STZ-induced diabetic mice, the plant extract may have anti-hyperglycemic action.

Because body weight is the best sign of good health and efficient metabolic balance, the effect of repeated daily administration of *Crinum abyssinicum* hydro-alcoholic shoot tips extract on body weight change in STZ-induced diabetic mice was investigated (Table 6). Over the course of the investigation, the body weight of normal control mice increased gradually. Increased treatment duration, on the other hand, resulted in a considerable reduction in the body-weight of untreated diabetic mice. This conclusion is consistent with a previous study by Jayaprasad et al, which found a similar reduction in body weight in STZ-induced diabetic mice. In STZ-induced diabetic control mice, significant ($p < 0.001$) body weight loss was observed. Dehydration, protein breakdown, and muscle atrophy are thought to be the causes of body weight loss in diabetic mice due to the lack of carbohydrates as an energy source and fat catabolism.⁶⁹ These data revealed that after 14 days of therapy, GLC5mg/kg and all doses of the extract-treated mice gained considerable weight ($p < 0.001$, $p < 0.01$) in comparison to the diabetes control group and baseline body weight, respectively. The extract's ability to reduce hyperglycemia may be linked to its beneficial effect on body weight loss. The extract's ability to reduce hyperglycemia may be linked to its beneficial effect on body weight loss. In this study, the phytochemical contents of *Crinum abyssinicum* may aid in body weight gain by decreasing free radical production owing to hyperglycemias, enhancing glucose utilization, and thus preventing muscle atrophy or sparing protein catabolism in extract-treated diabetic mice.

According to the findings, there are clear links between DM coexisting with hyperlipidaemia, DM, and hyperlipidemia, as well as death.⁷⁰ Increased STC, STG, LDL, and HDL levels, as well as decreasing HDL levels, are usually related to diabetes, which leads to the development of cardiovascular illnesses.⁷¹ The current investigation found a consistent positive connection between hyperglycemia and hyperlipidaemia. Hyperlipidemia makes diabetic people more vulnerable to cardiovascular disease. Due to an accelerated breakdown of lipid and free fatty acids from peripheral deposits in insulin shortage, it is regarded as a complication of diabetes mellitus. This explains why untreated diabetic mice have higher levels of STC, STG, and LDL but lower levels of HDL. Hyperglycemia is also associated with an increase in the contents of lipid profiles such as STC, STG, and LDL, as well as a decrease in the contents of HDL. STZ-induced diabetic control mice revealed dramatically increased content in STC, STG, and LDL, as well as decreased HDL, as expected. As shown in Table 7, repeated administration of CACE for 14 days lowered STC, STG, and LDL levels, but increased HDL content in a dose-dependent manner. However, it is unclear whether the crude extract from shoot tips was directly involved in lipid metabolism or whether the anti-hyperlipidaemic effect was achieved only as a result of reduced hyperglycemia. In STZ-induced diabetic rats, *Centratherum anthelminticum* ethanolic seeds extract exhibited a significant reduction in BGL, STC, STG, and LDL, as well as an increase in HDL levels.⁷²

Conclusions

To summarize, this is the first preliminary phytochemical and pharmacological study of *Crinum abyssinicum* shoot tips. It can be concluded from the findings of this study that the plant extract is safe for mice. According to preliminary findings, the crude extract can significantly lower blood glucose levels in diabetic, normoglycemic, and oral glucose-loaded mice.

Furthermore, in diabetic mice treated with plant extracts, a reduction in weight loss and hyperlipidemia was seen. These findings provide scientific evidence for the plant's stated usage in Ethiopian folk medicine to treat diabetes mellitus. Further research into the mechanism of this plant's anti-diabetic properties should be conducted using quantitative phytochemical screening tests, in vitro anti-oxidant tests, and histopathological tests. Furthermore, bioactivity-guided research is required to isolate the lead molecule responsible for anti-diabetic activity.

Journal of Experimental Pharmacology

Dovepress

Publish your work in this journal

The Journal of Experimental Pharmacology is an international, peer-reviewed, open access journal publishing original research, reports, reviews and commentaries on all areas of laboratory and experimental pharmacology. The manuscript management system is completely online and includes a very quick and fair peer-review system. Visit <http://www.dovepress.com/testimonials.php> to read real quotes from published authors.

Submit your manuscript here: <https://www.dovepress.com/journal-of-experimental-pharmacology-journal>
