Purpose: This study aimed to investigate the effectiveness of the simplified intervention, consisting of fluid and caffeine management alone in older women with overactive bladder symptoms.

Patients and Methods: A quasi-experimental pretest-posttest design was used. Rural, community-dwelling older women were recruited at four senior centers in South Korea. Of the 63 participants initially enrolled, 34 met the inclusion criteria. One group (n = 15) used fluid and caffeine management alone (FM), and the other group (n = 12) used a combination of fluid and caffeine management and pelvic floor muscle training (FM+PFMT). Urinary symptom-specific health-related quality of life was measured using the Korean version of KHQ. Sleep quality was measured using the Pittsburgh Sleep Quality Index. After the intervention, participants were assessed 4 and 8 weeks. A linear mixed model was used for the analysis.

Results: The mean age of the participants was 74.44 ± 5.67 years. Among the nine domains of KHQ, impact on life and physical limitations decreased significantly in both groups, without significant between-group differences. Sleep/energy increased in both groups, and the scores in the FM+PFMT group were significantly improved. The number of micturition episodes per day and the quality of sleep did not differ significantly between the two groups.

Conclusion: A simplified intervention, consisting of fluid and caffeine management alone can be considered as the first-line intervention to improve health-related quality of life in rural, community-dwelling, older women with overactive bladder symptoms. Healthcare providers should consider providing a relatively simple, but equally effective intervention to maximize the adherence and effectiveness.

Keywords: overactive urinary bladder, behavior therapy, quality of life, treatment adherence and compliance, nursing

Introduction

Overactive bladder (OAB) is defined as the presence of

urinary urgency, usually accompanied by frequency and nocturia, with or without urgency urinary incontinence (UUI), in the absence of urinary tract infection or other obvious pathology.¹

According to the population-based studies, the prevalence of OAB syndrome is 11.8–16.5% in adults aged 18 years and older in Europe, Canada, and the US, and 20% in adults aged 40 years and older in Asia.^{2–4} The prevalence is 30–40% in adults aged 75 years and older.³ OAB is not life-threatening but, it may have a negative effect on quality of life.⁵

A combination of behavioral and pharmacologic interventions is effective for managing OAB in older adults.⁶ Behavioral interventions can be categorized into lifestyle modification and training techniques.⁷ Lifestyle modification includes fluid management and weight control, avoiding bladder irritants in the diet, and timed voiding.⁷ Training techniques include bladder training with pelvic floor muscle (PFM) contraction to control urinary urgency, and regular pelvic floor muscle training (PFMT).⁷

Fluid management with caffeine reduction is simple and easy to implement in community-dwelling older adults with OAB.⁸ Previous studies have shown that reducing caffeinated coffee consumption and appropriate fluid intake is associated with alleviation of OAB symptoms.^{9,10} OAB symptoms and urinary incontinence (UI) can be made worse by excessive fluid intake and incontinence, whereas restriction of fluids may promote urinary urgency and frequency due to an increase in urine concentration, which may irritate the bladder mucosa.¹¹ The daily volume of fluid intake should be approximately 1500 mL or 30 mL/kg per 24 hours.¹² Hashim and Abrams¹³ found that OAB symptoms significantly decreased in patients who decreased their fluid intake by 25%. In their study,¹³ participants' average fluid intake and output volumes were greater than 1500 mL and 1700 mL per day, respectively. That is, fluid reduction may only be effective on OAB symptoms in adults who have appropriate fluid intake.¹³ In contrast, Park et al⁸ reported that the average volume of fluid intake in older women living in a rural area in Korea was approximately 934 mL per day. Thus, health care providers should confirm patients' daily fluid intake status before advising them to increase or decrease fluid intake.

Caffeine promotes detrusor muscle instability and has a diuretic effect. A high caffeine intake is associated with OAB.¹⁴ Specifically, older women in rural areas of South Korea (hereafter, Korea) have a high prevalence of lack of a formal education, overweight or obesity, and high caffeine consumption compared with the general population.^{6,15,16} Thus, lifestyle change behavioral interventions should be considered as the first option for older women in rural areas, and interventions should be simple to initiate and maintain.

PFMT was also effective in alleviating various lower urinary symptoms, such as urgency, stress or mixed UI.¹⁷ Because PFM contraction decreases detrusor pressure, increases urethral pressure, and suppresses the micturition reflex, patients with OAB are taught to perform PFM contractions when they feel an urge to urinate, instead of rushing to the toilet. Consequently, patients with OAB who perform PFM contractions may feel comfortable going to the toilet and avoid urinary leakage. In addition, PFMT may cause pelvic floor changes, and can normalize urethral pressure and the micturition reflex.¹⁸ Thus, correct contractions of the PFM and continued adherence to PFMT are crucial for the effectiveness of this approach.

However, correctly contracting the PFM and continued adherence to PFMT can be challenging for community-dwelling and rural-living older women. Talasz et al¹⁹ found that about 66% of older women were unable to perform PFM contractions, while 22% of them performed insufficient PFM contractions. Approximately one-third of women performed correct PFM contractions after receiving brief instructions,²⁰ but PFMT adherence tended to decrease over time.²¹ Considering the balance of efficacy, simplicity, and long-term adherence, it is not clear which behavioral interventions should first be recommended for community-dwelling older adults. Thus, in this study, we compared the effectiveness of using fluid and caffeine management alone versus using a combination of fluid and caffeine management with PFMT among community-dwelling older women with OAB in Korea.

Materials and Methods

Design

The current study had a quasi-experimental pretest-posttest design.

Participants

Community-dwelling older women who had OAB symptoms were recruited through four senior centers. These senior centers, which are places where older adults build friendships and participate in social activities, were selected from Gapyeong, Gyeonggi Province, South Korea. The four senior centers were randomized to two FM and two FM+PFMT sites. The enrolled participants were assigned to the FM or FM+PFMT group based on their place of residence, geographically close to a particular senior center, to minimize intervention-control contamination.

Participants were considered to have OAB if they answered "yes" on the question, "In the past month, have you had any experience of the sudden urge to urinate?" and answered "about once a daily", "2–4 times a day", or "5 times a day or more" on the question, "how often do you have a sudden desire to urinate that is difficult to defer?" The first question was originally developed by Irwin et al² and used in the Korean study.²² The second question was one from Overactive Bladder Symptom Score.²³ To check for a urinary tract infection, a urine dipstick test was used. Using an ultrasound bladder scanner (BioCon-700, Mcube Technology, Seoul, Korea), potential participants' post-void residual urine volume was measured within 5 min after they

voided. To avoid confounding effects, we excluded older women who had a urinary tract infection, had more than 100 mL of post-void residual urine, or had taken medicine for lower urinary tract symptoms.

Sample Size

For sample size calculation, we applied repeated-measures analysis of variance, with an effect size of 0.8 and a confidence level of 0.05, using the G*Power program (version 3.1.2). The required sample size was 27 per group. Considering a possible dropout rate of 30%, the recruitment target was set to 35 participants per group. Sixty-three participants eventually enrolled through the recruitment announcement. Of the 63 participants who were initially enrolled, 34 met the inclusion criteria. For the pilot study, a minimum sample size of 12 per group was recommended.²⁴

A CONSORT flow diagram, illustrating the flow of participants from recruitment to analysis, is presented in Figure 1. Of the 34 participants, 18 were assigned to the FM group, and 16 were assigned to the FM+PFMT group. Twenty-seven participants (79.4%) completed data collection at baseline and received the intervention.

Figure 1 Flow chart of the research process.

Intervention

The FM+PFMT group received education regarding fluid and caffeine management, combined with PFMT, and the FM group received education regarding fluid and caffeine management only. The principal investigator provided one-time group education at the senior center. The detailed content and timing of the education are presented in Table 1. None of the participants had any health problems requiring restriction of fluid intake. To ensure the appropriate volume of fluid intake a day, which is approximately 1500mL, participants were instructed to use a 300 mL water bottle to measure their daily fluid intake. They were advised increase or decrease their fluid intake based on their daily amount. In addition, for caffeine management, participants received information on caffeinated coffee and energy drinks, and were encouraged to avoid them.

The participants in the FM+PFMT group received verbal instructions on PFMT, based on the literature.²⁵ The standard established recommendation for PFMT was provided (ie, three sets of 10 exercises, performed three to four times a week). It was also recommended that participants conduct fast twitching of the PFM several times whenever they felt urgency, before going to the toilet. To monitor adherence to fluid and caffeine management and PFMT, participants were asked to write a daily log recording whether they performed the intervention.

Measurement

Health-Related Quality of Life

Urinary symptom-specific health-related quality of life (HRQOL) was the primary outcome and measured using the Korean version of the King's Health Questionnaire (KHQ).^{26,27} The instrument is a 21-item questionnaire based on nine domains including "general health perceptions", "impact on life", "role limitation", "physical limitation", "personal relationship", "social limitation", "emotion", "sleep/energy", and "incontinency severity". The score for each domain ranges from 0 to 100. A higher score indicates a lower HRQOL. Cronbach's α for the Korean version was 0.92²⁸ and that obtained in this study was 0.84.

Sleep Quality

Sleep quality was the secondary outcome and was assessed using the Korean version of the Pittsburgh Sleep Quality Index (PSQI-K).^{29,30} The instrument is a 19-item, self-rated questionnaire and the scores range from 0 to 21. A higher score indicates lower sleep quality. Cronbach's α of the Korean version was 0.84²⁹ and that in this study was 0.67.

Participants' Characteristics

Information was collected on participants' age, level of education, living status, self-reported health status, number of micturition episodes per day, and self-reported comorbidities.

Table 1 Overview of the Content of the Intervention

FM group		FM+PFMT Group	
Fluid and caffeine modification	Time (minutes)	Fluid and caffeine modification + PFMT	Time (minutes)
Overview of OAB Basic bladder anatomy and micturition process Sign and symptoms of OAB	15	Overview of OAB Basic bladder anatomy and micturition process Signs and symptoms of OAB	15
Fluid and caffeine modification Appropriate daily fluid intake Caffeinated drinks: coffee, energy drinks, green tea	15	Fluid and caffeine modification Appropriate daily fluid Caffeinated drinks: coffee, energy drinks, green tea	15
Q & A	10	Break Unassisted PFMT and practice Q & A	10 30 10
Total education time	40	Total	80

Abbreviations: OAB, overactive bladder; FM, Fluid and caffeine modification; PFMT, pelvic floor muscle training.

Data Collection

In this study, data were collected from February to April 2018. At the four senior centers, face-to-face, structured interviews were conducted by trained research assistants. After collecting the baseline data, the interventions were provided by the principal investigator on the same day at the rural senior center. After the intervention was provided, the research assistants who participated in the data collection called all participants once a week to monitor their adherence to the intervention and encourage them to maintain adherence. Data were collected at 4 and 8 weeks after the intervention for posttest 1 and posttest 2, respectively.

Ethical Considerations

This study complies with the ethical principles of the Declaration of Helsinki. This study was approved by the institutional review board of Yonsei University (No. Y-2017-0106). Written informed consent was obtained. All participants were informed of the aims, procedures, and possible benefits and risks of the study, and their right to withdraw at any time during the research process. They were informed that all data would be used for research purposes only.

Data Analysis

Descriptive statistics were used to describe participants' demographics and disease-related characteristics. The homogeneity between the FM+PFMT and FM groups was evaluated using the independent *t*-test, the chi-square test, and Fisher's exact test. Between-group differences were analyzed using a linear mixed model. All statistical analyses were based on the intention-to-treat population. For the missing data, last observation carried forward (LOCF) method was used. The data were analyzed with SAS version 9.4 (SAS Institute, Cary, NC, USA).

Results

The baseline characteristics of the 27 participants are presented in Table 2. There were no significant differences in the general characteristics of the FM and FM+PFMT groups. The mean age of the participants was 74.44 ± 5.67 years. Thirty-three percent of the participants did not have any formal education, and 51.9% of them had completed elementary

Table 2 Comparison of General Characteristics and Main Variables Between the FM and FM+PFMT Groups at Baseline (N=27)

Incontinence severity	31.60 ± 19.18 (6.67–73.30)	33.33 ± 19.19 (6.67–60.00)	29.44 ± 19.79 (6.67–73.33)	−0.52 (0.610)

Note: ^an=5; ^bn=3.

Abbreviations: SD, standard deviation; FM, Fluid and caffeine modification; PFMT, pelvic floor muscle training.

school education (6 years of education). The mean body mass index was 25.59 ± 3.69 kg/m², and 70.4% of the participants were overweight or obese. Fifty-two percent of participants lived with their spouses. The most prevalent health problems were hypertension (55.6%) and musculoskeletal disease (40.7%).

The mean number of micturition episodes per day was 7.93 ± 3.31 . The mean sleep quality score measured by the PSQI-K was 10.19 ± 3.52 , meaning that participants' sleep quality was poor. On the KHQ, participants reported slightly poor general health perceptions (56.48 ± 24.61) and a minor impact on life related to their bladder problems (41.97 ± 32.80). Participants reported that the other domains of KHQ were not strongly affected by their bladder problems, as follows: role limitations (17.28 ± 22.40), physical limitations (25.31 ± 28.26), social limitations (13.58 ± 23.13), personal relationships (4.17 ± 11.79 ; n = 8), and emotions (11.11 ± 21.35). Regarding the personal relationships with their partner, only eight participants responded to the question because 13 participants (48.2%) were widowed. Most participants with spouses responded as "not applicable" to the questions, "Does your bladder problem affect your relationship with your partner?" and "Does your bladder problem affect your sex life?", and the data were treated as missing according to KHQ scoring system. Therefore, the variables regarding personal relationships were not included in the linear mixed model analysis.

The mean values, standard deviations, and results of the linear mixed model analysis for outcome variables are presented in Table 3. Regarding the primary outcome of urinary symptom-specific HRQOL, the scores on the KHQ domains for "the impact on life" and "physical limitations" related to bladder problems decreased significantly over time in both groups (p = 0.010, p = 0.027, respectively). However, in both groups, "incontinence severity" fluctuated over time (p = 0.036). "Sleep/energy" increased over time in both groups (p = 0.006), and a significant group-by-time interaction effect was noted (p = 0.049; Figure 2). While the scores of "sleep/energy" in the FM group improved minimally, these scores improved significantly in the FM+PFMT group. No significant differences between two groups by time were found in the other domains of the KHQ. Regarding the secondary outcome—the quality of sleep—measured by the PSQI-K or the number of micturition episodes per day, there were no differences between the two groups over time.

Discussion

Current guidelines have suggested the use of behavior therapy that combines training techniques with habit changes as a first-line treatment for OAB.^{1,30} However, unassisted interventions, including Kegel exercises, are often difficult for older women to follow because they struggle to identify the correct muscles to confirm whether they are performing the exercise properly. In this study, we showed that, over time, behavioral interventions—both a simplified fluid and caffeine management and a combination of fluid and caffeine management with PFMT—were significantly effective in improving the impact of OAB symptoms on life and the physical limitations related to OAB symptoms, with no significant differences between the two groups. These findings support our hypothesis that a simplified intervention, ie, fluid and caffeine management alone, can be considered as a first-line behavioral intervention, as it is equally effective in alleviating the effects of OAB symptoms on life and physical limitations as is PFMT combined with fluid and caffeine management.

In this study, there were no significant differences between the intervention and FM+PFMT groups in any of the outcomes, except for the sleep and energy variables in the KHQ. Considering that the effect of PFMT on OAB depends on several factors, such as the frequency and extent of training, adherence to the training procedure, functional performance of PFM, and satisfaction with the intervention,^{31,32} one possible explanation of the negative findings in the current study is that the FM+PFMT group participants might not have performed PFMT correctly based on unsupervised verbal instructions, without vaginal palpation or ultrasound monitoring. According to previous systematic reviews, supervised PFMT programs were more effective in reducing UI than non-supervised programs.^{33–35}

In reality, however, it is not possible to provide supervised PFMT programs to women living in rural areas, because of limited facilities and human resources. In rural areas of Korea, there are few specialized healthcare providers that can care for patients with OAB and that can supervise PFMT interventions, as these are mainly provided by secondary or tertiary hospitals. In addition, for women who live in rural areas, far from specialized clinics, there are limited resources for learning how to perform PFMT in home-based exercises or for attending supervised PFMT programs. Therefore, to change behaviors in Korean women living in rural areas, it is important to consider the tolerability, simplicity, and ease of adherence to behavioral interventions, in addition to the efficacy of the interventions.

This study had several limitations. First, the evaluation of intervention adherence and compliance may not have been accurate because the study data were based on self-reporting via daily log sheets and a telephone follow-up interview. Specifically, all participants were encouraged to consume 1500 mL of fluids. For older women living in rural areas, with

low education levels, we designed a simple logging method using simple marking rather than writing the amount of fluid intake. However, we found that it was not easy for these women to mark a daily log consistently, while following the intervention instructions. For future studies, we suggest that a pre-survey should be conducted to identify which intervention logging methods are appropriate for older women living in rural areas (eg, using daily accomplishment stickers, rather than writing in a diary).

Second, during the intervention process, it was difficult to ensure accurate evaluation of whether participants performed PFMT properly, because we did not employ an objective measure of effective contractions of the PFM, such as a biofeedback devices or digital muscle testing. Instead, based on the daily log sheet and a telephonic follow-up interview, we considered them to be compliant with the verbal instructions of PFMT if they had completed 60% of the full instructions (three sets of 10 muscle training exercises per day). Thus, future studies should include objective measurements that test PFM contraction, to improve the internal validity of such an experimental study.

Third, in this study, data were collected at 4 and 8 weeks after the intervention. Depending on the severity of their OAB, some participants experienced the effect of the intervention within 2 weeks and up to 3 months or longer.^{36,37} Therefore, future studies need to consider a longer follow-up period to better measure the effects of PFMT and the fluid moderation intervention. Moreover, to avoid confounding effects, the current study excluded older women who had a urinary tract infection, had more than 100 mL of post-void residual urine, or were taking medication for lower urinary tract symptoms. In addition, for increasing the accuracy of the amount of participants' intake and output and urinary symptoms of OAB, future studies should consider including a voiding diary or pad use.

Additionally, in the current study, 27 participants of the 34 enrolled participants remained, which implies a 20.6% attrition rate. This attrition rate may be attributed to seasonal effects, because this study was conducted from February to April 2018, which is a busy farming season. Therefore, we suggest that considering farming events is important when conducting research in rural areas. As another strategy to decrease the attrition rate during the intervention period, regular monitoring, such as encouraging intervention adherence by a telephone call once a week or using an online-video individual/group meeting, can be considered. It is also important to include gatekeepers, such as community nurses and leaders, in an advisory board to identify user-friendly interventions and to develop alternative retention plans, thereby maximizing the benefit–burden ratio.³⁸ Future intervention studies including older adults living in rural areas should consider the benefits of the potentially helpful intervention and social interactions, as well as the burdens of discomfort, time, and accessibility, associated with study participation.

Finally, this pilot study had a small sample size and was conducted in a single county in Korea. Due to the small size of the senior centers in the rural area, finding participants with OAB was difficult. Nurses at the health center confirmed this difficulty, even with ample time set aside for recruitment. Therefore, generalizing our findings to other older adults with OAB symptoms should be undertaken with caution. Based on the results of this pilot study, a replication study that expands the geographic area and number of participants should be undertaken in the future. Moreover, to improve the generalizability of the study findings, environmental factors and social interactions should be considered for a multilevel assessment of participant characteristics that could affect the results.

Conclusion

This study found that fluid and caffeine management can be considered as the first-line intervention among various behavioral interventions for rural, community-dwelling older women with OAB. For those who have difficulty in performing and adhering to proper PFMT, healthcare providers should consider education on a relatively simple, but equally effective intervention, ie, fluid management including caffeinated drink reduction to maximize adherence and to optimize the effectiveness of behavioral interventions.

Acknowledgments

We would like to express our gratitude to the women from Gapyeong County who participated in this study and to the nurses of the community health centers.

Journal of Multidisciplinary Healthcare

Dovepress

Publish your work in this journal

The Journal of Multidisciplinary Healthcare is an international, peer-reviewed open-access journal that aims to represent and publish research in healthcare areas delivered by practitioners of different disciplines. This includes studies and reviews conducted by multidisciplinary teams as well as research which evaluates the results or conduct of such teams or healthcare processes in general. The journal covers a very wide range of areas and welcomes submissions from practitioners at all levels, from all over the world. The manuscript management system is completely online and includes a very quick and fair peer-review system. Visit <http://www.dovepress.com/testimonials.php> to read real quotes from published authors.
