Purpose: Subsets of non-small-cell lung cancer patients with epidermal growth factor receptor (EGFR) mutations carry uncommon subtypes. We evaluated the efficacy of first-generation EGFR-tyrosine kinase inhibitors (TKIs; erlotinib, gefitinib, and icotinib) in patients with non-small-cell lung cancer carrying insertions and T790M and S768I mutations in EGFR exon 20.

Patients and methods: Patients carrying EGFR exon 20 insertion/T790M/S768I mutations and treated with EGFR-TKIs were evaluated from 2005 to 2014 in Zhejiang Cancer Hospital. The efficacy was evaluated using the Kaplan–Meier method and compared with the log-rank test.

Results: Sixty-two patients with exon 20 insertion/T790M/S768I mutations were enrolled. Mutations including exon 20 insertions and T790M and S768I mutations were observed in 29, 23, and ten patients, respectively. In total, the response rate and median progression-free survival (PFS) were 8.1% and 2.1 months, respectively. Patients with S768I mutation manifested the longest median PFS (2.7 months), followed by those with T790M (2.4 months) and exon 20 insertions (1.9 months; $P=0.022$). Patients with complex mutations show a better PFS than those with single mutations (2.7 months vs 1.9 months; $P=0.034$).

Conclusion: First-generation EGFR-TKIs are less effective in patients with exon 20 uncommon mutations than in those with common mutations. Patients with complex mutations benefited more from first-generation EGFR-TKIs than those with single mutations.

Keywords: non-small cell lung cancer, epidermal growth factor receptor, EGFR mutations, exon 20, tyrosine kinase inhibitor

Introduction

Lung cancer is the leading cause of cancer-related deaths in the People's Republic of China.¹ Non-small-cell lung cancer (NSCLC) constitutes ~70%–80% of all lung cancers.² Somatic mutations within the epidermal growth factor receptor (EGFR) gene were discovered in a subset of NSCLC patients, especially in East Asian female patients with adenocarcinoma.^{3–6} Treatments targeting EGFR mutations incorporate EGFR inhibitors such as gefitinib and erlotinib, resulting in extended survival and increased quality of life in patients with NSCLC.^{7–10}

Two major EGFR-activating mutations include an in-frame deletion in exon 19 (del 19) and an L858R substitution in exon 21. These mutations account for ~90% of all clinically important mutations related to EGFR-tyrosine kinase inhibitor (TKI) sensitivity.^{11,12} In addition, other uncommon mutations have been identified. Among these, the G719X in exon 18 and L861Q in exon 21 have been frequently reported. The published data demonstrate moderate sensitivity of these two mutations to EGFR-TKI treatment, resulting in a median progression-free survival (PFS) of ~6 months.^{13–15}

T790M mutation, S768I mutation, and insertions have been identified in exon 20. Owing to the rarity of these subtypes, the mutations have not been fully described.^{16,17} The efficacy of EGFR-TKIs in patients harboring these mutations to EGFR-TKIs is still unknown.

This study investigated the clinical characteristics and efficacy of EGFR-TKIs in patients carrying uncommon mutations in EGFR exon 20.

Patients and methods

This study conducted from 2005 to 2014 at the Zhejiang Cancer Hospital (People's Republic of China) included patients with known EGFR genotypes and treated for advanced NSCLC using EGFR-TKIs (gefitinib, erlotinib, or icotinib). The protocol was reviewed and approved by the Ethics Committee of Zhejiang Cancer Hospital. All patients provided written informed consent.

EGFR mutational analysis

The tumor EGFR mutational status was determined by analyzing the DNA extracted from formalin-fixed, paraffin-embedded tumor tissues or from cytology samples. All samples were tested using an amplification refractory mutation system-based EGFR mutation detection kit (Amoy Diagnostics, Xiamen, People's Republic of China). The method enabled the detection of 29 mutations in exons 18, 19, 20, and 21. In exon 20, two mutations (S768I and T790M) and one insertion were included.

Efficacy evaluation

Tumor responses were assessed based on the Response Evaluation Criteria in Solid Tumors Version 1.1. Objective tumor responses included complete response (CR), partial response (PR), stable disease (SD), and progressive disease. Objective responses included the CR and PR. Disease control rate was defined as the addition of objective response and stabilization rates (CR + PR + SD).

Statistical analysis

PFS and overall survival (OS) were estimated using the Kaplan–Meier method. The log-rank test was used to compare the PFS and OS in different patients. PFS was calculated from the starting date of EGFR-TKIs treatment until the date of disease progression or death. The OS was measured from the date of initial dosing of EGFR-TKIs until the date of the last follow-up or death. All statistical analyses were performed using Statistics 17.0 (SPSS Inc., Chicago, IL, USA). The median follow-up time was 18.5 months (range 5.0–36 months), and the last follow-up date was August 1, 2015.

Results

Patient profile

Between January 2005 and July 2014, 3,910 patients were evaluated for EGFR mutations. The results showed that 2,350 patients (60.1%) carried wild-type EGFR and 1,560 patients harbored EGFR mutations. Eighty-nine patients carried exon 20 mutations, including 62 treated with EGFR-TKIs. The clinical profile of patients is listed in Table 1. Patients included 39 males and 23 females with a median age of 60 years. Thirty-one patients were smokers or ever-smokers. The performance status of 0–1 was observed in 82.3% patients, while a performance status of 2 or 3 was seen in eleven patients. Histologically, adenocarcinoma was the most common subtype (56 cases, 90.3%), and adenosquamous or large cell carcinoma occurred in six patients. At the start of EGFR-TKI treatment, two patients were diagnosed with stage IIIB carcinoma and 60 with stage IV. The 62 patients included 34 with single and 28 with complex mutations. Twenty-nine patients carried an

insertion, twenty-three showed T790M mutation, and ten carried S768I mutation (Table 2).

Efficacy of exon 20 mutations

The efficacy of EGFR-TKIs in patients was evaluated. The response data are shown in Table 3. The patient response rate and disease control rate were 8.1% and 54.8%, respectively. Among these, absence of CR, five cases of PR, and 29 cases of SD were confirmed. The median PFS and OS in all patients were 2.1 months and 13.3 months, respectively.

In the subset analysis, patients with S768I mutation had the most favorable PFS (median, 2.7 months), followed by those with T790M (median, 2.4 months) and insertion (median, 1.9 months) mutations ($P=0.022$; Figure 1A). However, no differences in OS were observed among the three groups (Figure 1B). The PFS of EGFR-TKIs treatment in eleven patients exceeded 6 months (Table 4).

Patients with single mutations had significantly shorter PFS than did patients with complex mutations (2.7 months vs 1.9 months, $P=0.034$; Figure 2A). No efficacy difference was found among single S768I, insertion, and T790M mutation patients (2.4 months vs 1.9 months vs 1.8 months, $P=0.457$). The OS of patients with single and complex mutations was not significantly different (Figure 2B).

Table 3 Efficacy of EGFR-TKIs in patients with EGFR exon 20 mutations

Mutation type	CR	PR	SD	PD	ORR (%)	DCR (%)	PFS (months)	OS (months)
S768I (n=10)	0	2	5	3	20	70	2.7	14.5
20 insertion (n=29)	0	2	11	16	6.90	44.80	1.9	12.9
T790M (n=23)	0	1	13	9	4.30	49.10	2.4	13.5

Abbreviations: EGFR, epidermal growth factor receptor; TKI, tyrosine kinase inhibitor; CR, complete response; PR, partial response; SD, stable disease; PD, progressive disease; ORR, overall response rate; DCR, disease control rate; PFS, progression-free survival; OS, overall survival.

Efficacy comparison with common mutations

In total, 742 patients treated with first-generation EGFR-TKIs were selected among 1,560 patients harboring EGFR mutations. Among these 742 patients, 592 had deletion in exon 19 and L858R substitution in exon 21 (group A), 71 had exon 18 G719X and exon 21 L861Q (group B), 62 had exon 20 mutations (group C, current study data), and 17 had other mutations (group D). The PFS of groups A, B, C, and D with EGFR-TKIs treatment was 10.8 months, 6.2 months, 2.1 months, and 3.3 months, respectively ($P=0.015$). The OS difference also varied among groups A and B and groups C and D (25.5 months vs 21.7 months, 13.3 months vs 16.5 months, respectively $P=0.041$).

Discussion

To the best of our knowledge, this is the first study that specifically demonstrated the clinical efficacy of EGFR-TKIs in patients with exon 20 mutations as inferior to that of patients with common EGFR mutations. We also found that patients with exon 20 complex mutations have better PFS and OS than those carrying a single mutation.

The frequency of uncommon mutations ranged from 10% to 18%.^{18–21} The most common mutation was G719X in exon 18, followed by L861Q in exon 21.^{13–15} These two mutations were moderately sensitive to first-generation EGFR-TKIs with a median PFS of ~6 months. Exon 20 mutations including insertions, S768I, and T790M are relatively rare compared with L861Q and G719X according to previous reports.^{16,17} In the present study, the frequency of exon 20 mutation was 5.7%, which is consistent with previous studies.

The efficacy of EGFR-TKIs against exon 20 mutations is debatable.^{18,20,21} A preclinical study showed that the S768I mutant was resistant to EGFR-TKIs.²² By contrast, several small case studies demonstrated the clinical efficacy to EGFR-TKIs in patients carrying S768I mutations.^{23,24} In this study, ten patients were identified with S768I mutations with a clinical efficacy inferior to that of the other common mutations, but better than other exon 20 mutations (Figure 1).

The PFS was 2.7 months with afatinib treatment in 23 patients harboring exon 20 insertion mutation in the study of Yang et al,²⁵ suggesting that patients with this uncommon mutation may benefit from treatment with EGFR-TKIs. The PFS of exon 20 insertions was inferior to that in the study of Yang et al in the current cohort, which may be related to the first-generation EGFR-TKIs used.

In contrast to exon 20 insertions, most of the T790M mutations were concurrent with common mutations. Although considered as a common resistance mutation in patients who progressed from EGFR-TKIs treatment, only ~1%–2% of patients harbored the de novo T790M mutation.^{19,25} Patients with this mutation responded to EGFR inhibitors, but with a shorter PFS than in patients with common mutations.²⁵ In our cohort, 23 patients were confirmed with T790M de novo mutation, and the median PFS was 2.4 months. The results suggest that EGFR-TKIs benefited certain groups of patients. For patients with de novo T790M mutation, the emphasis on third-generation EGFR-TKIs targeting this mutation may be a better choice in future clinical practice.

In the present study, we found that the therapeutic efficacy against single mutations was inferior to that of complex mutations (Figure 2A). However, the efficacy difference of first-generation EGFR-TKIs for patients with single mutations did not exist. Eight of eleven patients with PFS >6 months harbored complex mutations in the current study (Table 4). We suggest that the treatment recommendations should focus on complex but not single mutations.

The current study is limited by the small size and a retrospective design.

The second-generation EGFR-TKIs demonstrated better efficacy than the first-generation products.^{25,26} Due to the nonapproval in the People's Republic of China, no data of patients treated with second-generation EGFR-TKIs were collected in the present study. The polymerase chain reaction-based amplification refractory mutation system method was used in the current study, which failed to cover all the insertion mutations in exon 20 and probably skewed the results.

Conclusion

Our results suggest that the efficacy of the first-generation EGFR-TKI treatment against the EGFR exon 20 mutations was inferior to treatments targeting the common mutations. The therapeutic efficacy in patients who harbored exon 20 mutations, concurrent with other common mutations, was better than in those carrying a single mutation. The efficacy of new drugs targeting the rare mutations needs to be elucidated in future studies.
