Objective: Osteoarthritis (OA) is characterized by progressive matrix destruction of articular cartilage. This study aimed to investigate the potential antioxidative and chondroprotective effects and underlying mechanism of Icariin (ICA) in interleukin-1 beta (IL-1 β)-induced extracellular matrix (ECM) degradation of OA cartilage.

Methods: Human chondrocyte cell line HC-A was treated with different doses of ICA, and then MTT assay and PI staining were used to estimate ICA-induced chondrocyte apoptosis. Intracellular ROS and superoxide dismutase (SOD) and glutathione peroxidase (GPX) were measured after treatment by IL-1 β with or without ICA. The mRNA and protein expression levels of redox transcription factor Nrf2 and the downstream effector SOD-1, SOD-2, NQO-1 and HO-1 were assayed to explore the detailed mechanism by which ICA alleviates ECM degradation. Finally, to expound the role of Nrf2 in ICA-mediated chondroprotection, we specifically depleted Nrf2 in human chondrocytes and then pretreated them with ICA followed by IL-1 β .

Results: ICA had no cytotoxic effects on human chondrocytes and 10⁻⁹ M was selected as the optimum concentration. ROS induced by IL-1 β could drastically activate matrix-degrading proteases and ICA could significantly rescue the matrix degradation and excess ROS generation caused by IL-1 β . We observed that ICA activated the Nrf2/ARE pathway, consequently upregulating the generation of GPX and SOD. Ablation of Nrf2 abrogated the chondroprotective and antioxidative effects of ICA in IL-1 β -treated chondrocytes.

Conclusion: ICA alleviates IL-1 β -induced matrix degradation and eliminates ROS by activating the Nrf2/ARE pathway.

Keywords: icariin, Nrf2 signaling, ROS, human chondrocyte, ECM degradation

Introduction

Osteoarthritis (OA) is a common chronic joint disease characterized by the degradation and destruction of the mesenchondrium. The main pathological processes of osteoarthritis include ageing, oxidative stress, inflammation and changes in catabolism-related gene expression.¹⁻³ As demonstrated in several studies, inflammatory responses play a key role in the pathogenesis of OA, owing to the extracellular matrix (ECM) degradation caused by inflammatory mediators.^{4,5} An increasing number of studies have demonstrated that cellular inflammation and ECM degradation are crucial for the progression of OA.

Interleukin-1 (IL-1) was the first interleukin to be identified and has served as a ground-breaking molecule with implications extending far beyond its extended

family. IL-1 affects virtually all cells and organs and is a major pathogenic mediator of autoinflammatory, auto-immune, infectious and degenerative diseases. The effect of IL-1 on the central nervous system include fever and activation of the hypothalamus-pituitary-adrenal (HPA) axis. Cortisol downstream of HPA axis has a regulatory function on innate immunity and inflammation.^{6–10}

IL-1 α and IL-1 β , are encoded by distinct genes, bind to the same receptor (IL-1R1) and have similar biological properties. However, distinctions do exist and impact on immunity, inflammation and cancer. The IL-1 α precursor is constitutively present in epithelial layers of the entire gastrointestinal tract, lung, liver, kidney, endothelial cells, and astrocytes. Upon cell death by necrosis, as occurs in ischemic diseases such as myocardial infarction, stroke, acute renal failure and tumor necrosis, the IL-1 α precursor is released. Unlike the IL-1 β precursor, the IL-1 α precursor is fully active and functions as an “alarmin” by rapidly initiating a cascade of inflammatory cytokines and chemokines, which accounts for sterile inflammation.^{11,12} Thus, IL-1 α mediates the early phases of sterile inflammation. In addition to the IL-1 α precursor released from necrotic cells, there is a membrane form of IL-1 α present on activated monocytes. However, circulating IL-1 α is rarely detected even in persons with severe infections but is contained in apoptotic bodies released from endothelial cells.¹³

IL-1 β , a key pro-inflammatory cytokine that signals primarily through the type 1 IL-1 receptor (IL-1R1), plays an important role in OA. IL-1 β is produced as a 269-amino-acid precursor that is cleaved by IL-1 β -converting enzyme (ICE) to the active IL-1 β form that is secreted.¹⁴ Some studies have shown that IL-1 signaling is opposed by the naturally occurring peptide IL-1 receptor antagonist, which is a therapeutic agent for the treatment of arthritis.¹⁵ The IL-1 β signaling cascade represents a highly conserved response to various pathological processes, including OA. Conversely, the IL-1 β pathway can, in turn, aggravate OA by accelerating ECM degradation and inducing excess ROS generation and the expression of prostaglandin E2 (PGE2) and nitric oxide (NO).^{16,17} Hence, in this study, we used IL-1 β to simulate the in vitro inflammatory response of chondrocytes to septic arthritis. In addition, we found that IL-1 β -induced inhibition of pathophysiological processes, such as ECM degradation, was an effective strategy for the treatment of OA.

NF-E2-related factor 2 (Nrf2) is a sensitive redox transcription factor in the leucine zipper family, and Kelch-like ECH-associated protein 1 (Keap1) is its specific repressor. Nrf2/Keap1 signaling mediates cellular responses to oxidative

stresses and a series of electrophilic xenobiotics.^{18–20} Under normal conditions, Nrf2 exists in the cytoplasm, combining with Kelch-like epoxy chloropropane-related protein 1 (Keap1) in the form of a dipolymer. However, in response to an oxidative stress source, the configuration of Keap1 changes, leading to the dissociation of Nrf2 in the cytoplasm. Nrf2 is then phosphorylated for transfer into the nucleus, where it combines with the antioxidant reaction element (ARE) to regulate a variety of antioxidant enzymes and protect the cell, including activation of the expression of SOD-1, SOD-2, HO-1 and NQO-1.^{18,21} A great deal of research has shown that the Nrf2/Keap1 pathway is actually responsible for defending tissues against the effects of chronic inflammation and cancer by preventing oxidative stress.^{19,22}

Herba epimedii, a perennial herb of the berberidaceae that is rich in flavonoids and lignin compounds, has validated curative effects in the treatment of several age-related diseases including osteoporosis, sexual dysfunction and OA.^{23,24} Icarin (ICA) (chemical structure see Figure 1A) is the major pharmacologically active flavonol diglycoside of herba epimedii, which has been shown to promote matrix formation, including the facilitation of bone matrix generation. Additionally, the anti-inflammatory effect of ICA is known to be mediated through the suppression of NF-kappaB activity and upregulation of SIRT6 enzyme activity in vitro.^{25–27} Understanding of the chondroprotective effects of ICA is gradually emerging owing to research using a rat osteoarthritis model and or chondrosarcoma cells.^{28,29} Additionally, ICA has been shown to have an antioxidant effect in human chondrocytes, which might be associated with its chondroprotective effects.³⁰

However, the relationship between antioxidative and chondroprotective effects induced by ICA is not clear. Moreover, the chondroprotective effect of ICA has not been explored in detail, and reports concerning the underlying mechanisms are lacking. Therefore, the present research was undertaken to verify the chondroprotective effects and underlying mechanism of ICA using IL-1 β -induced human chondrocytes. Our results demonstrate that ICA inhibits IL-1 β -induced matrix degradation and catabolic responses through a reduction of ROS excess generation by induction of the Nrf2/ARE pathway in human chondrocytes.

Materials And Methods

Treatment Of Human Chondrocytes With IL-1 β Or ICA

Human chondrocytes-Adult (HC-A) (Sigma, TX, USA) (1×10^6 /well of 6-well plate) were seeded in Dulbecco's

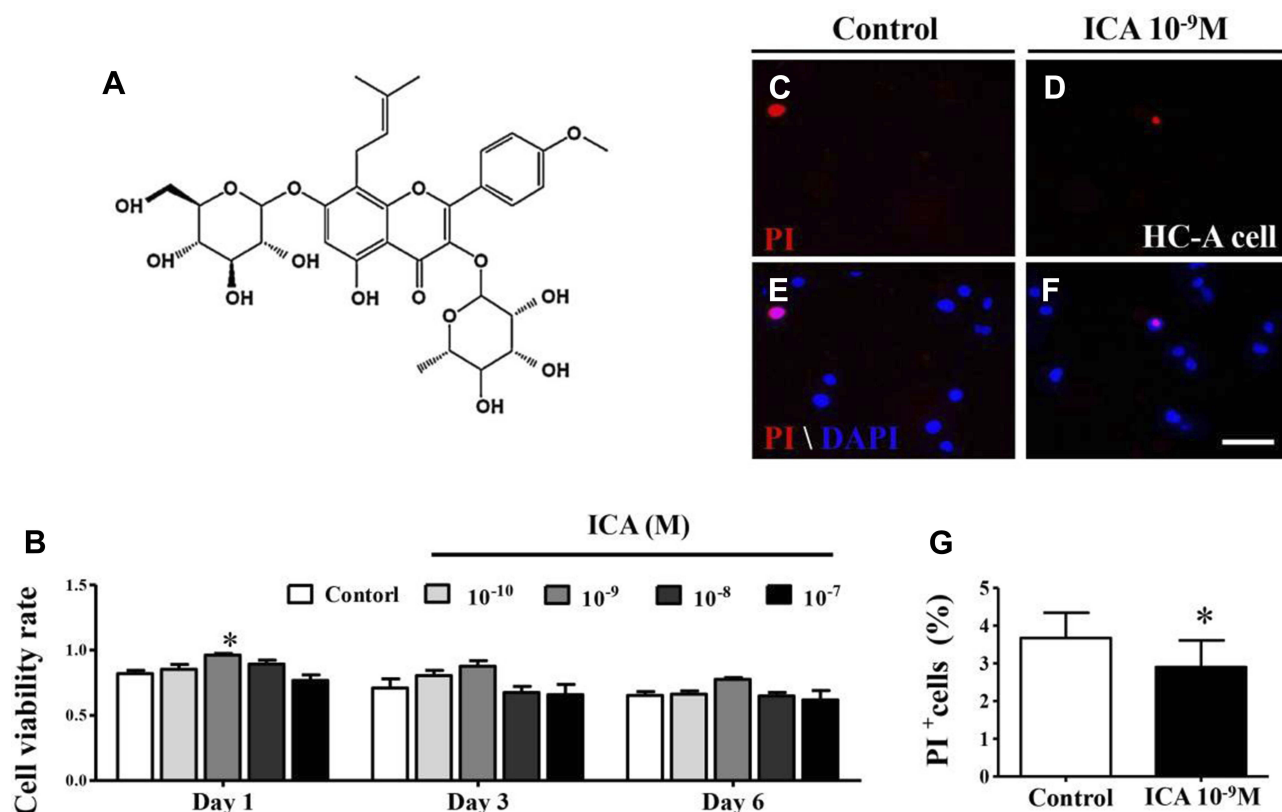

Figure 1 ICA at 10^{-9} M exerts no cytotoxic effects on the HC-A cell line. (A) The chemical structure of ICA. (B) Bar chart showing HC-A cell viability after 0.1% DMSO or 10^{-10} – 10^{-7} M ICA treatment for 24 h, 72 h and 6 days using the MTT assay. (C–F) PI staining of HC-A cells cultured in 0.1% DMSO or 10^{-9} M ICA for 24 h. (G) Bar chart comparing the percentage of PI⁺ cells in control or ICA cultures. Scale bars = 100 μ m in (B–E). Data are expressed as the mean \pm SD (n = 6). *p \leq 0.05, compared to the control.

Modified Eagle's Medium/Nutrient Mixture F-12 (DMEM/F-12) supplemented with 10% fetal calf serum (FCS), 100 units/mL penicillin, and 100 mg/mL streptomycin for 2–3 days after plating. At approximately 80% confluence, they were serum-starved overnight and then treated with different concentrations of ICA (Sigma, TX, USA) for 2 h followed by stimulation with IL-1 β (1 ng/mL) (Pepro Tech, NJ, USA). Chondrocytes treated with 0.1% DMSO served as a control.

Cell Culture And MTT Assay

HC-A were cultured in a humidified incubator at 37 °C and 5% CO₂ in 96-well plates. The cells (1×10^6 cells mL⁻¹) were maintained in Dulbecco Minimal Eagle's Medium (Gibco, Carlsbad, CA, USA) plus 10% fetal bovine serum (Australia origin, Gibco, Carlsbad, CA, USA). ICA (10^{-10} – 10^{-7} M, 72 h) or simple saline (control) was added to the HC-A cultures. Cell viability was assessed using a modified MTT assay. Briefly, 10 μ l of MTT solution (5 mg/mL in phosphate-buffered saline) was added to the 96-well plates and incubated continually

for 4 h at 37 °C. The MTT solution was then removed, and formazan dye was dissolved in dimethyl sulfoxide (Sigma-Aldrich) for 10 min by shaking. The absorbance values were measured at 570 nm using a Bio-Rad Model 450 Microplate Reader (Bio-Rad). The cell viability was indirectly determined by examining the ratio of the absorbance value of ICA-treated cells relative to the control. The final results were determined by analyzing three independent experiments. GAPDH used as control and none of treatment group affect the GAPDH.³¹

Estimation Of Apoptosis By Propidium Iodide (PI) Staining

Chondrocytes (1×10^6 /well of 6-well plate) were treated with ICA (10^{-10} – 10^{-7} M) for 72 h, and ICA-induced chondrocyte apoptosis was estimated by PI staining. In brief, the chondrocytes were cultured, washed twice with cold PBS, and then incubated with PI for 45 min at 37 °C in the dark. All cells were counterstained with DAPI (1:1000, Invitrogen) at room temperature.

Measurement Of Intracellular Reactive Oxygen Species

Intracellular ROS were determined using the nonfluorescent dye 2',7'-dichlorodihydrofluorescein diacetate (Sigma-Aldrich), which is oxidized by ROS generated by cells into a fluorescent dye 2',7'-dichlorofluorescein. The control group, IL-1 β (1 ng/mL), and IL-1 β + NAC (10 mM)-treated HC-A cells were incubated in the presence of 10 μ M 2',7'-dichlorodihydrofluorescein diacetate for 20 min. The fluorescence was measured using a BD FACS Aria (Becton, Dickinson and Company, Franklin Lakes, NJ, USA).

Superoxide Dismutase And Glutathione Peroxidase (GPX) Assays

Oxidative stress was assessed by measuring the superoxide dismutase (SOD) and glutathione peroxidase (GPX) levels in the developing YSM. SOD and GPX activities were elucidated using commercial kits (Nanjing, Jiangsu Province, China). The results from the control group, IL-1 β (1 ng/mL) or IL-1 β + NAC (10 mM)-treated samples were analyzed based on the differences in their respective fluorescein decay curves.

RNA Isolation And qPCR Analysis

Total RNA was isolated from chondrocytes (1×10^6 /well in a 6-well plate) using a TRIzol kit (Invitrogen, USA) according to the manufacturer's instructions. These chondrocytes were pretreated with NAC (10 mM) or ICA (10^{-9} M) for 2 h, followed by treatment with IL-1 β (1 ng/mL) for 24 h. First-strand cDNA synthesis and the SYBR® Green qPCR assay was performed using a PrimeScript™ RT reagent kit (Takara, Japan). Reverse transcription and amplification reactions were performed in Bio-Rad S1000™ (Bio-Rad, USA) and ABI 7000 thermal cyclers, respectively. Analysis of an invariant endogenous control gene, GAPDH, was performed in parallel to confirm that equal amounts of RNA were used in each reaction. The ratio between the intensity of fluorescently stained bands corresponding to the genes and GAPDH was calculated to quantify the transcript levels of those genes. The RT-qPCR results are representative of three independent experiments. The amplicon sequenced done by Sanger sequencing. GAPDH used as control and none of treatment group affect the GAPDH.

Morphometry Of Chondrogenic Matrix Production By Cultured Cells

Proteoglycan synthesis of cultured cells was evaluated by Alcian blue staining as previously described.³² In short,

the cultured cells were fixed in 95% ethanol and then stained with 1% Alcian blue dye (pH 1.0) overnight at room temperature. The stained cartilage nodules that were formed in the presence of 10^{-9} M ICA or IL-1 β were photographed and counted using an inverted microscope (Nikon Eclipse Ti-U, Japan). After treatment, the cultures were examined at 72 h. The average size (area) of the chondrogenic nodules was digitized as the total stain intensity/nodule number. The final results were acquired by analyzing 3 independent experiments.

Glycosaminoglycan (GAG) Assay

After treatment for 72 h, the agarose cell specimens were dissolved and centrifuged at 300 g for 10 mins at 4 °C, which provided a pellet containing cells with their cell-associated matrix. To determine the GAG amounts, the pellets were digested for 12 hrs at 55 °C in papain buffer (200 μ g/mL papain in 50 mmol/L EDTA, 5 mmol/L L-cysteine, pH 3.0) (Sigma Chemical, USA). GAG was quantified using the dimethylmethylene blue assay.³³ The metachromatic reaction of GAG with dimethylmethylene blue was monitored using a spectrophotometer, and the A_{540}/A_{595} ratio was used to determine the amount of GAG using chondroitin sulfate C (Sigma Chemical, USA) as a standard.

Western Immunoblotting

After treatment with DMSO or IL-1 β 1 ng/mL for 24 h, or pretreatment with ICA (10^{-9} M) for 2 h followed by IL-1 β (1 ng/mL) for 24 h, chondrocytes were harvested and proteins isolated using an extraction kit (Beyotime Institute of Biotechnology, Jiangsu, China), separated by sodium dodecyl sulfate polyacrylamide gel electrophoresis, and transferred onto polyvinylidene fluoride membranes (Bio-Rad, USA). Membranes were blocked in 5% bull serum albumin (Sigma, TX, USA) for 2 h and then incubated with primary antibodies overnight at 4 °C. Blots were then incubated with horseradish peroxidase-conjugated secondary antibody, followed by washing with TBST (Bio-Rad, USA). Blots were developed using Luminata Western HRP substrate (EMS Millipore, USA), and antibody reactive proteins were visualized by chemiluminescence and imaged using the PxiGel imaging system (Syngene, Frederick, MD).

siRNA-Mediated Depletion Of Nrf2 Expression Using Nucleofection

Human chondrocytes were transfected with 100 nM Nrf2 siRNA (SMART pool: ON-TARGET plus NFE2L2 siRNA

Dharmacon, Lafayette, CO, USA) or MISSION® siRNA Universal Negative Controls (Sigma Aldrich, St. Louis, MO) using the P3 Primary Cell 4D-Nucleofector™ X Kit on 4D-Nucleofector equipment (Lonza, Walkersville, MD) following the instructions provided by the manufacturers. Transfected cells were plated in 6-well plates. Forty-eight hours after transfection, the cells were serum-starved overnight, followed by treatment with ICA (10^{-9} M) for 2 h, and then stimulation with IL-1 β (1 ng/mL) in serum-free medium for 24 h. Gene expression levels were measured by Western blotting.

Statistical Analyses

The values are presented as the mean \pm SD, and statistically significant differences between the experimental groups and controls were analyzed by one-way ANOVA followed by post hoc analyses using the Tukey's test. Unless otherwise noted, each experiment was repeated three times using three independent samples. $P < 0.05$ was considered statistically significant.

Results

ICA At 10^{-9} M Exerts No Cytotoxic Effect On The Viability Of Human Chondrocytes

Icariin (chemical structure see [Figure 1A](#)) (Sigma, TX, USA), the major pharmacologically active flavonol diglycoside of *Herba Epimedii*, has potential chondroprotective effects, as previously reported.^{28,34} To confirm the chondrogenic phenotype of a monolayer culture of human chondrocytes-adult (HC-A) (Sigma-Aldrich, USA) treated with ICA, we examined the viability of the chondrocytes using the MTT assay. Compared with the untreated control, ICA treatment (10^{-10} ~ 10^{-7} M, 72 h) had no effect on chondrocyte viability at day 1, day 2 or day 3 ([Figure 1B](#)). Furthermore, the absence of a cytotoxic effect of ICA was confirmed by PI staining at 24 h ([Figure 1C-F](#)), and no increases in apoptosis or necrosis were observed in chondrocytes incubated with ICA (10^{-9} M) for 24 h compared with untreated control chondrocytes ([Figure 1G](#)).

IL-1 β -Induced ROS Production Plays An Important Role In The Activation Of Genes Or Proteases Related To Matrix Degradation

Several studies have demonstrated that ROS production is the crucial pathophysiological change during inflammation progression in articular cartilage.^{35,36} In our study, the

intracellular ROS production assay demonstrated that IL-1 β could significantly increase ROS generation after treatment for 24 h, which was clearly inhibited by NAC ([Figure 2B](#)). These chondrocytes were pretreated with NAC (10 mM) for 2 h followed by IL-1 β (1 ng/mL) for 24 h or IL-1 β alone. The results obtained for GPX and SOD activity further reinforced this mechanism ([Figure 2C and D](#)).

N-acetylcysteine (NAC), an admittedly efficacious scavenger of ROS, has been utilized to demonstrate whether ROS production is necessary for the activation of genes related to ECM degradation and GAG disintegration.^{37,38} Therefore, to investigate whether IL-1 β -induced ROS generation was the main cause of the activation of matrix-degrading proteases in chondrocytes, we performed qRT-PCR to examine the expression of genes related to matrix degradation.

Our results showed that IL-1 β -stimulated human chondrocytes presented a significant upregulation of the mRNA expression of MMP-3, -9, -13 and ADAMTS-4, whereas treatment with NAC clearly reversed this effect, especially for the expression of MMP-13 and ADAMTS-4 ([Figure 2E](#)). These chondrocytes were pretreated with NAC (10 mM) for 2 h followed by IL-1 β (1 ng/mL) for 24 h or with IL-1 β alone. In addition, the results of the GAG assay further supported that the reduction of ROS could rescue the synthesis of GAG ([Figure 2F](#)). The chondrocytes used in the GAG assay were pretreated with NAC (10 mM) for 2 h followed by IL-1 β (1 ng/mL) for 24 h or IL-1 β alone, and then cultured in a humidified incubator at 37 °C and 5% CO₂ for an additional 48 h. Taken together, these results suggested that the activation of genes or proteases related to matrix degradation is principally caused by IL-1 β -induced ROS instead of a direct effect of IL-1 β .

ICA Can Significantly Reduce The Matrix Degradation Caused By IL-1 β

ICA (chemical structure shown in [Figure 1A](#)), the major pharmacologically active flavonol diglycoside of *Herba Epimedii* as shown in some studies, has certain chondroprotective effects;^{30,34} however, the specific underlying mechanism is still unknown.

The chondrocyte micromass culture model has been widely used to simulate cartilaginous ECM formation. In micromass cultures, chondrogenesis is initiated when the chondrocytes begin to condense and aggregate to form large nodules.^{35,36,39} These nodules appear morphologically like cartilage and will begin to produce an extracellular matrix (ECM) after several days of culture.⁴⁰ Thus, this model was employed to investigate whether ICA

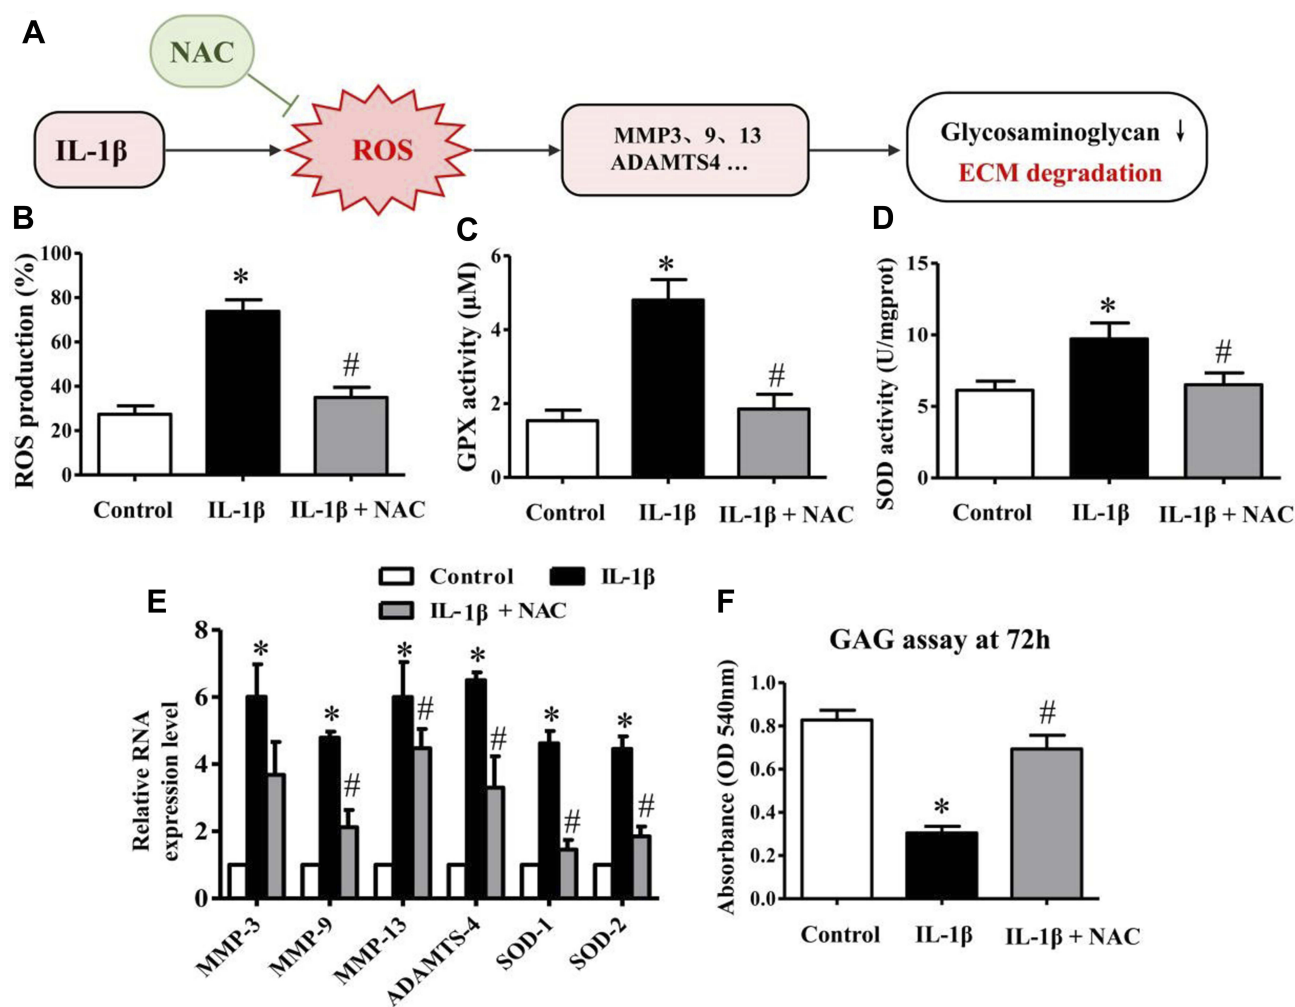

Figure 2 Matrix-degrading proteases are activated by excess ROS production induced by IL-1 β . **(A)** Schematic drawing summarizing the relationship between IL-1 β , ROS and ECM degradation according to the following charts. **(B)** Bar charts showing intracellular ROS production level after treatment with 0.1% DMSO alone, IL-1 β 1 ng/mL for 24 h, and pretreatment with NAC (10 mM) for 2 h followed by IL-1 β (1 ng/mL) for 24 h. The fluorescence was then measured to detect the percentage of positive cells using a BD FACS Aria (Becton, Dickinson and Company, Franklin Lakes, NJ, USA). **(C-D)** Bar charts showing GPX and SOD activities in the different above-described groups. **(E)** After the different treatments described above, RNA expression levels of MMP-3, -9, -13, ADAMTS-4, SOD-1 and SOD-2 in chondrocytes were measured by quantitative PCR using the TaqMan assay system (Life Technologies). GAPDH was used as an endogenous control. **(F)** The glycosaminoglycan (GAG) assay was performed after the above-described treatments. After an additional 48-h incubation, GAG synthesis was significantly inhibited following chondrocyte treatment with IL-1 β , and the inhibitory effect of IL-1 β on GAG synthesis was significantly reversed when chondrocytes were pretreated with NAC. Data are expressed as the mean \pm SD (n = 6). * p \leq 0.05, compared to the control; # p \leq 0.05, compared to IL-1 β .

could reduce the matrix degradation caused by IL-1 β , as identified by Alcian blue staining.

In our study, the chondrocytes were treated with DMSO, or IL-1 β 1 ng/mL for 24 h, or pretreated with ICA (10^{-9} M) for 2 h followed by IL-1 β (1 ng/mL) for 24 h, and then cultured in a humidified incubator at 37 $^{\circ}$ C and 5% CO $_2$ in 6-well plates for an additional 48 h and stained with Alcian blue. In the presence of IL-1 β (1 ng/mL), a dramatic reduction in nodule formation was observed in the cultures (Figure 3B and C), implying that IL-1 β could inhibit ECM secretion and chondrogenesis. In contrast, ICA reversed the inhibitory effect of IL-1 β on ECM secretion (Figure 3D). We also quantitatively determined the extent of ECM formation by measuring the

area of Alcian blue staining after exposure to IL-1 β or ICA for 72 h (Figure 3E), which further revealed that ICA could exert a chondroprotective effect by reducing the ECM reduction caused by IL-1 β .

To further assess whether this phenomenon was involved in the change in matrix-degrading related genes, we performed quantitative PCR. The results demonstrated that IL-1 β stimulation of human chondrocytes led to a significant upregulation of the mRNA expression of MMP-3, MMP-9, MMP-13 and ADAMTS-4, whereas treatment with ICA, conversely, exerted a suppressive effect on the expression of all these enzymes (Figure 3F). GAG synthesis was significantly inhibited when chondrocytes were treated with IL-

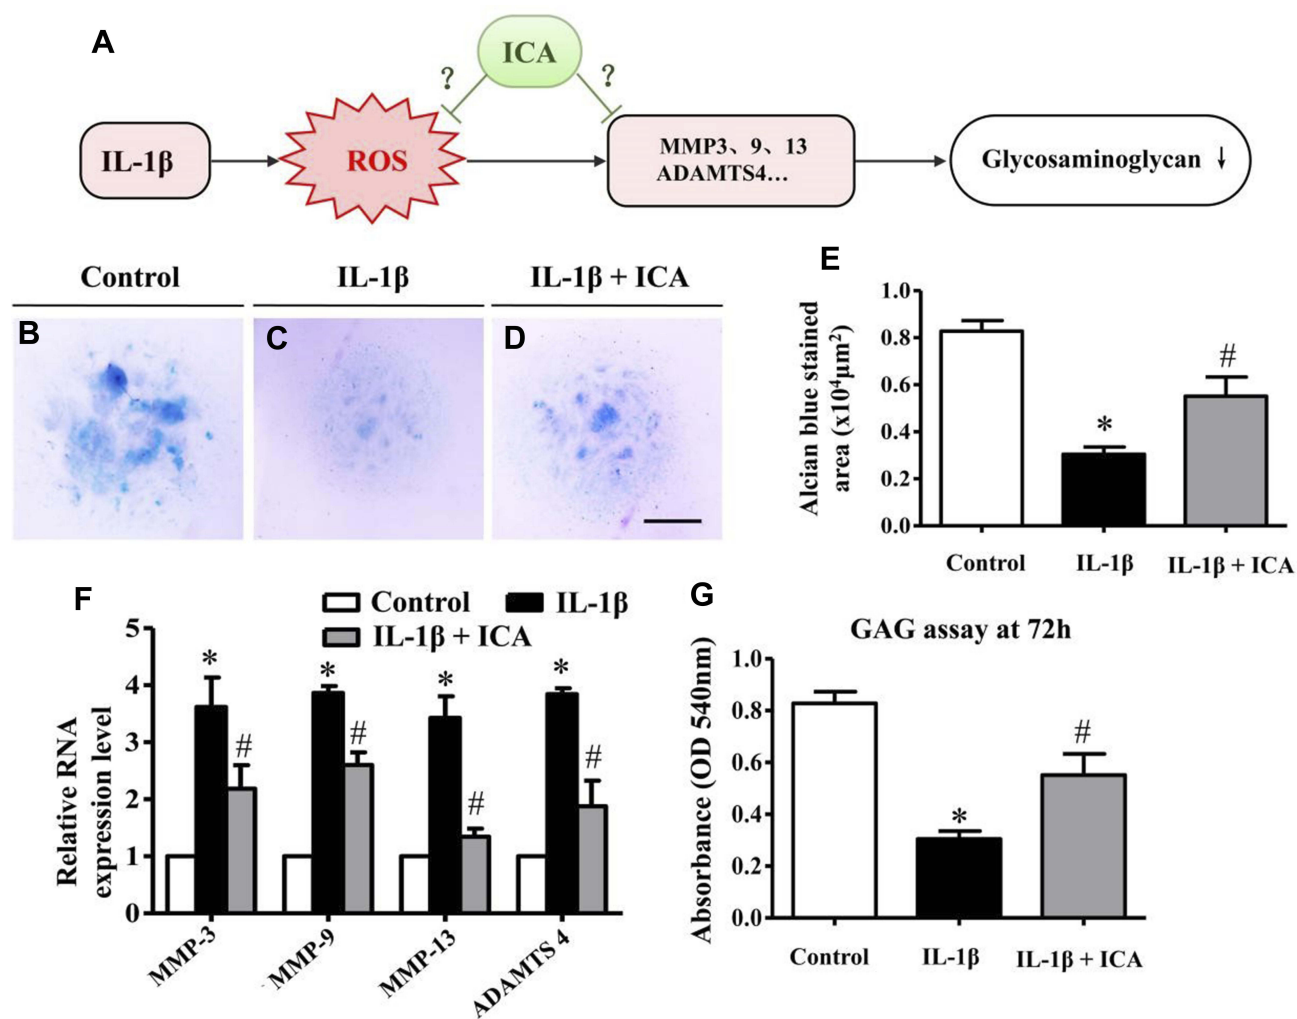

Figure 3 ICA can significantly rescue the matrix degradation caused by IL-1 β . **(A)** Schematic drawing summarizing the relationship between IL-1 β , ROS and ECM degradation according to the following charts, with the unknown mechanism of ICA. **(B-D)** Representative micrographs of HC-A cell mass micromass cultures treated with DMSO or IL-1 β 1 ng/mL for 24 h, or pretreated with ICA (10^{-9} M) for 2 h followed by IL-1 β (1 ng/mL) for 24 h, and culturing in a humidified incubator at 37 °C and 5% CO₂ for an additional 48 h and Alcian blue staining. **(E)** Bar chart showing the average size (area) of the chondrogenic nodules formed after 72 h. **(F)** The expression levels of Nrf2, Keap1, SOD-1, SOD-2 and HO-1 were measured by quantitative PCR using the TaqMan assay system (Life Technologies). GAPDH was used as an endogenous control. **(G)** The GAG assay was performed after treatment with 0.1% DMSO alone, IL-1 β 1 ng/mL for 24 h, or pretreatment with ICA (10^{-9} M) for 2 h followed by IL-1 β (1 ng/mL) for 24 h. Scale bars = 500 μ m in (B-D). Data are expressed as the mean \pm SD (n = 6). *p \leq 0.05, compared to the control; #p \leq 0.05, compared to IL-1 β .

1 β , and the inhibitory of IL-1 β on GAG synthesis was reversed when chondrocytes were pretreated with ICA for 2 h before addition of IL-1 β (Figure 3G).

Taken together these results demonstrated that ICA could be an effective inhibitory agent for the suppression of matrix-degrading proteases in IL-1 β -induced chondrocytes.

ICA Activates The Redox Sensitive Transcription Factor Nrf2 In Human Chondrocytes

As mentioned previously, although the chondroprotective effect of ICA has been affirmed, the detailed mechanism by which ICA alleviates ECM degradation is still unknown.

Since ROS is the main contributing factor to ECM degradation under IL-1 β induction as proved (Figure 2A), and ICA can obviously suppress the expression of matrix-degrading proteases (Figure 3A), we hypothesized that treatment with ICA might reduce ECM degradation by means of alleviating oxidative stress and eliminating ROS.

As reported in a large body of literature, Nrf2 is a crucial redox transcription factor that functions in restraining oxidative stress.⁴¹⁻⁴⁴ To examine whether ICA achieves its chondroprotective function by activating the Nrf2/ARE pathway and eliminating ROS, we examined the expression of the Nrf2/ARE pathway at both mRNA and protein levels.

First, we measured the activation of the Nrf2/ARE pathway in human chondrocytes by detecting protein synthesis by Western blotting. The chondrocytes were treated with DMSO or IL-1 β 1 ng/mL for 24 h or pretreated with ICA (10^{-9} M) for 2 h followed by IL-1 β (1 ng/mL) for 24 h and then harvested and subjected to protein isolation. A significant upregulation of Nrf2 and its downstream proteases was detected after ICA treatment (Figure 4A and B). In addition, ICA could eliminate a considerable amount of ROS (Figure 4D). Furthermore, it dramatically promoted SOD and GPX viability, which may have led to the reduced ROS levels (Figure 4C and E).

Finally, to further substantiate the role of ICA in the Nrf2 pathway at mRNA level, RT-qPCR was performed to assess Nrf2 and the downstream expression of Nrf2 effectors in human chondrocytes treated with DMSO or IL-1 β 1 ng/mL for 24 h or pretreated with ICA (10^{-9} M) for 2

h followed by IL-1 β (1 ng/mL) for 24 h. The results indicated that treatment with ICA could considerably induce the mRNA expression of SOD-1, SOD-2, NQO-1 and their downstream target gene HO-1 in human chondrocytes, the downregulation of Keap1 also indicated that ICA could inhibit formation of the Nrf2/Keap1 dipolymer (Figure 4F).

Corroborating these data, we can assume that ICA can activate Nrf2/ARE pathway and, consequently, eliminate ROS, likely eventually alleviating the ECM degradation.

Primer sequence done by Sanger sequencing are mentioned below.

GAPDH (202bp)

F: 5- TGTTGCCATCAATGACCCCTT-3

R: 5- CTCACGACGACTCAGCG-3

IL1 β (148bp)

F: TCAAACCTCTGGAGGAAGTGC

Figure 4 ICA reduces the ROS generation induced by IL-1 β by activating the Nrf2 pathway. (A) Protein expression of Nrf2, SOD-1 and SOD-2 was investigated by Western blotting using antibodies against the indicated protein, and β -actin was used as a control for equal loading. (B) Specific signal intensities normalized to β -actin were quantified using ImageJ software. (E) Bar charts showing SOD activities in the different groups. (F) The expression of Nrf2, Keap1, SOD-1, SOD-2 and HO-1 was measured by quantitative PCR using the TaqMan assay system (Life Technologies). GAPDH was used as an endogenous control. Data are expressed as the mean \pm SD (n = 6). * $p \leq 0.05$, compared to the control; # $p \leq 0.05$, compared to IL-1 β .

Genetic Ablation Of Nrf2 Abrogates The Chondroprotective And Antioxidative Effects Of ICA In IL-1 β -Treated Chondrocytes

Although we showed that ICA could activate the Nrf2/ARE pathway and reduce ROS production to alleviate matrix degradation, whether the Nrf2/ARE pathway played a prominent role in the function of ICA as an inhibitor of ECM degradation was still unknown.

To expound the role of Nrf2 in ICA-mediated chondroprotection, we specifically depleted Nrf2 in human chondrocytes and then pretreated them with ICA for 2 h followed by IL-1 β (1 ng/mL) for 24 h (Figure 5A and B). As demonstrated by the Western blotting results, siRNA-mediated depletion of Nrf2 significantly abrogated the ICA-induced suppression of MMP-13 (Figure 5A and D), and the GAG assay result further confirmed that the chondroprotective effect of ICA could be abrogated following depletion of the Nrf2 gene (Figure 5F).

In addition, the reduction of IL-1 β -induced ROS caused by ICA also disappeared following depletion of the Nrf2 gene (Figure 5E). Moreover, ICA-induced promotion of NQO-1 protein was also abrogated when Nrf2 was depleted (Figure 5A and C). Finally, the GPX and SOD activity results further substantiated the dramatic abrogation of the antioxidative effect of ICA following Nrf2 gene depletion (Figure 5G and H). Taken together, these results demonstrate that the Nrf2 pathway plays a key role in the ICA-mediated chondroprotective and antioxidative effects.

Discussion

Under physiological conditions, articular cartilage is in a state of homeostasis, consisting of chondrocytes and ECM, which is a strictly avascular environment with a low oxygen supply.^{45,46} However, oxidative stress can be triggered by various adverse factors, like inflammation, causing tremendous production of ROS. During pathological conditions, oxygen tension in synovial fluid is subject to fluctuation as a consequence of ischemia-reperfusion, pathological acceleration of tissue metabolism and sustained abnormal strains on the joint.^{47,48} The excess ROS can then lead to clear destruction of the cartilage matrix via several intracellular pathways, including cytokine receptors, receptor tyrosine kinases, receptor serine/threonine kinases and G protein coupled receptors. In addition, ROS have been shown to activate mitogen-regulated kinase (MAPK) pathways in several systems, including extracellular signal-regulated kinase

(ERK)1/2, Jun-NH2-terminal kinase and P38 MAPK cascades.^{40,49} Ultimately, various intracellular signaling events result in matrix degradation by mediating the activation of latent collagenase, which is involved in the upregulation of the matrix metalloproteinases (MMPs) family.^{50,51}

However, the cause of the increased expression of MMPs and ADAMTS-4 resulting from inflammation or subsequent ROS production necessitated further study. Hence, we investigated the effects of ROS induced by IL-1 β on ECM degradation and found, using NAC (an orthodox ROS scavenger), that the expression of MMPs and ADAMTS-4 mainly arose from ROS rather than a direct effect of IL-1 β (Figure 2).

ICA, a kind of plant-derived agent, has received considerable attention for its potential to serve as a substitute therapy for the treatment of OA. ICA exhibits antioxidative properties in various diseases,⁵²⁻⁵⁴ including diabetes and osteoarthritis. These findings suggest that ICA may have therapeutic potential for the promotion of ECM synthesis, which is significant to the treatment of OA.

Therefore, after elucidating the relationship between ROS generation and MMP activation (Figure 2), we exposed IL-1 β -treated chondrocytes to ICA. The results demonstrated that ICA could significantly alleviate the matrix degradation caused by IL-1 β (Figure 3), in accord with previous reports. To further investigate the mechanism by ICA rescued the matrix degradation, we employed a series of assays targeting intracellular ROS generation. The results revealed that the excess ROS generation could be reduced by ICA (Figure 4). Additionally, ICA activated the Nrf2/ARE pathway, consequently upregulating the generation of GPX and SOD, which strongly suggested that Nrf2/ARE signaling was involved in the mechanism of ICA-mediated chondroprotection (Figure 4). Taken together, these results indicate that ICA may alleviate matrix degradation by activating Nrf2/ARE signaling and eliminating excessive ROS.

Nevertheless, the actual mechanism of chondroprotection mediated by ICA can be fairly complex, and it may include other factors except the activation Nrf2/ARE signaling. Hence, whether activation of the Nrf2/ARE pathway is necessary for the inhibition of matrix-degrading is a crucial issue. Therefore, to expound the role of Nrf2/ARE signaling in ICA-mediated chondroprotection, we eventually resorted to transfection experiments. The results demonstrated that ablation of Nrf2 completely abrogated the chondroprotective and

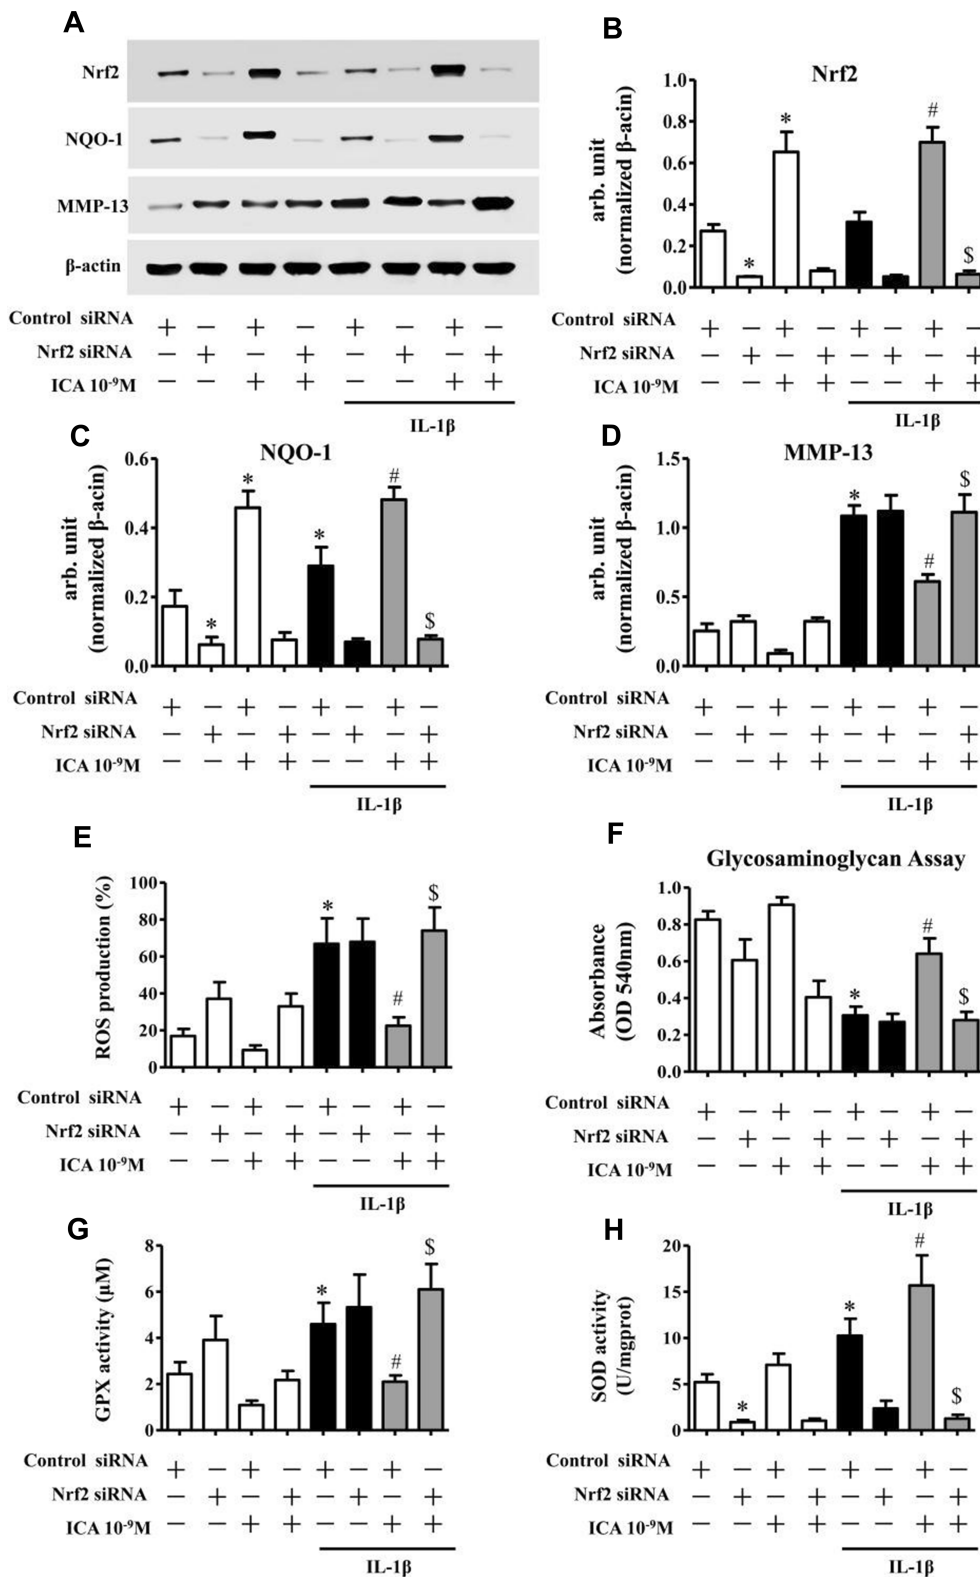

Figure 5 Ablation of Nrf2 abrogates the chondroprotective and antioxidative effects of ICA in IL-1β-treated chondrocytes. Genetic ablation of Nrf2 using specific siRNA abrogated the antidegradation effect of ICA in chondrocytes. Chondrocytes were transfected with siRNA specific for Nrf2 (100 nM) using nucleofection. Forty-eight hours after transfection, the OA chondrocytes were serum-starved, treated with Wogonin (10 μM) for 2 h and then stimulated with or without IL-1β (1 ng/mL) for 16 h. **(A)** The expression levels of Nrf2, NQO-1 and MMP-13 were investigated by Western blotting. β-actin was used as a control for equal loading. **(B-D)** Specific signal intensities normalized to β-actin were quantified using ImageJ software. **(E)** Bar chart showing the cellular ROS production level using the nonfluorescent dye 2,2'-dichlorodihydrofluorescein diacetate (Sigma-Aldrich). **(F)** Bar chart showing GAG synthesis using the dimethylmethylene blue assay. **(G-H)** Bar chart showing GPX and SOD activities using commercial kits (Nanjing, Jiangsu Province, China). Data are expressed as the mean ± SD (n = 6). *p < 0.05, compared to control siRNA; #p < 0.05, compared to control siRNA + IL-1β; \$p < 0.05, compared to control siRNA + IL-1β + ICA.

Figure 6 Schematic representation of the potential mechanism of ICA in Nrf2 activation and ROS elimination in IL-1 β -induced chondrocytes. IL-1 β causes excess ROS generation, whereas ICA treatment activates the redox-sensitive transcription factor Nrf2. ICA can disrupt the formation of Keap1-Nrf2 dipolymer by directly inhibiting the expression of Keap1, thereby interdicting the combination of Nrf2 and Keap1 protein and leading to activation and nuclear importation of Nrf2. Thus, activation of the Nrf2 pathway leads to transcription of the downstream genes SOD-1, SOD-2, NQO-1 and HO-1. The activation of ARE results in the reduction of ROS, consequently reducing the IL-1 β -induced matrix-degrading proteases and ECM degradation.

antioxidative effects of ICA in IL-1 β -treated chondrocytes (Figure 5), substantiating our hypothesis (Figure 6).

In conclusion, our research shows that ICA can activate Nrf2 to decrease oxidative stress, consequently reducing the degradation of cartilage matrix and revealing the cartilage-protective and antioxidation functions of ICA, based on activation of the Nrf2 signaling pathways. These findings offer an important theoretical basis for the admission of ICA to the clinical treatment of joint diseases. However, its clinical application requires further

research, and further studies are also needed to determine whether and how ICA activates Nrf2 upstream signaling molecules.

Drug Design, Development and Therapy

Dovepress

Publish your work in this journal

Drug Design, Development and Therapy is an international, peer-reviewed open-access journal that spans the spectrum of drug design and development through to clinical applications. Clinical outcomes, patient safety, and programs for the development and effective, safe, and sustained use of medicines are a feature of the journal, which has also

been accepted for indexing on PubMed Central. The manuscript management system is completely online and includes a very quick and fair peer-review system, which is all easy to use. Visit <http://www.dovepress.com/testimonials.php> to read real quotes from published authors.

Submit your manuscript here: <https://www.dovepress.com/drug-design-development-and-therapy-journal>
