Purpose: This study aimed to reveal the multicomponent synergy mechanisms of SWP based on network pharmacology and metabolomics for exploring the relationships of active ingredients, biological targets, and crucial metabolic pathways.

Materials: Network pharmacology, including TRRUST, GO, and KEGG, enrichment was used to discover the active ingredients and potential regulation mechanisms of SWP. LC-MS and multivariate data analysis method were further applied to analyze serum metabolomics profiling for discovering the potential metabolic mechanisms of SWP on AA induced by Cyclophosphamide (CTX) and 1-Acetyl-2-phenylhydrazine (APH).

Results: A total of 27 important bioactive ingredients meeting the ADME (absorption, distribution, metabolism, and excretion) screening criteria from SWP were selected. Interaction networks were constructed and validated based on the 10 associated ingredients with the relevant targets. A total of 125 biomarkers were found by Metabolomics approach, which associated with the development of AA, mainly involved in amino acid metabolism and lipid metabolism. While SWP can reverse the above 12 metabolites changed by AA. Network analysis revealed the synergistic effects of SWP through the 43 crucial pathways, including Sphingolipid signaling pathway, Sphingolipid metabolism, Arginine and proline metabolism, VEGF signaling pathway, Estrogen signaling pathway.

Conclusion: The study suggested that SWP is a useful alternative for the treatment of AA induced by CTX + APH. Its potential mechanisms are to improve hematopoietic microenvironment and promote bone marrow hematopoiesis therapies.

Keywords: aplastic anemia, Siwu Paste, network pharmacology, metabolomics, integration analysis

Introduction

Aplastic anemia (AA), a bone marrow hematopoietic failure (BMF) syndrome, is characterized by attenuated bone marrow hematopoietic cell proliferation, decreased peripheral whole blood cell and immune dysfunction.¹ It has high prevalence in the Asian population, especially young adults.² Chemotherapy is the most common cause of AA. Although the immunosuppressive therapy provide an strategy for patients who are not suitable for allogeneic hematopoietic stem cell transplant, some patients after treated with a single therapeutic method show relapse or poor efficacy.^{3,4} Therefore, expanding an alternative and more effective therapy for AA is needed. Moreover, the pathogenesis of AA induced by chemotherapy drugs is complex, and combination therapy may supply better service for it than monotherapy.

Siwu Paste (SWP), a popular prescription for tonifying blood, has over 1000 years history in the clinical application of Traditional Chinese Medicine (TCM). It described as good effects in promoting blood circulation, ameliorating anemia and pain, with the feature of, including four herbs: *Angelica sinensis* (Oliv.) Diels (Dang Gui, DG), *Ligusticum chuanxiong* Hort.

(Chuan Xiong, CX), *Cynanchum otophyllum* Schneid.(Bai Shao, BS) and *Rehmanniae radix* preparata (Shu Di Huang, SDH), in the ratio of 10:6:10:15, respectively.⁵ Our previous research suggested that SWP may alleviates hematopoietic functions via “multi-component and multichannel”, such as regulating the bone marrow hematopoiesis, improving blood rheology, inhibiting inflammation and exerting estrogen-like effects.^{6,7} Compared with other manners, paste is more convenient to carry. And it has better treatment compliance and lower economic burden in treatment of AA induced by chemotherapy drugs. Moreover, SWP at dose of 22.68g/kg has similar efficacy as Fu-Fang E’jiao Jiang.⁶ Although, the efficacy of SWP has been demonstrated, the potential mechanism of therapeutic effects of SWP on AA remains puzzled. It limits the application of SWP in experiment as well as clinic. Thus, a comprehensive study is necessary for discovering the relationships among the active ingredient, potential targets, and their molecular mechanisms of SWP in treating AA.

As a promising approach to discover TCM, network pharmacology links the chemical space of drugs to the biomolecular pathways of disease through network footprints. Li et al, conducted a network pharmacology analysis of Danggui Buxue Decoction and they found that the four chemical components (Z-ligustilide, E-butylidenephthalide, Z-butylidenephthalide and ferulic acid) played a major role in the blood enrichment effect.⁸ Wang et al, have demonstrated that tetramethylpyrazine and paeoniflorin enable the vessel to sprout by up-regulating ESR α mRNA expression.⁹ These studies provide a better basis for our understanding of AA, but network analysis alone cannot truly reflect the impact of multi-component SWP on the occurrence and development of AA. As a systematic method, metabolomics provides a series of particular and sensitive markers for disease diagnosis and drug treatment. The differences between AA patients and healthy, and the therapeutic effects of TCM on AA were studied. Zhong et al, analyzed the difference of serum metabolites between 40 healthy control and 40 AA patients. Comparing with the control groups, they found that the levels of aminoacyl-tRNA biosynthesis, ATP binding cassette transporters, and amino acid biosynthesis were increased markedly in AA, while the TCA cycles was decreased dramatically.¹⁰ Liet al, employed GC/MS technology to provide an evidence that *Angelica sinensis* intervene 5 metabolic pathways (Arachidonic acid metabolism, citrate cycle (TCA), glycine, serine and threonine metabolism, arginine and L-proline metabolism and valine, leucine and isoleucine biosynthesis) to repair the metabolic disorders resulted from AA.¹¹ He et al, speculate that SWP down-regulate the levels of 3 amino acids (L-Methionine, L-Tyrosine, and L-Phenylalanine) in plasma metabolites compared with AA model group, but it up-regulate the Hippuric acid, Deoxycholic acid and Sphingosine-1-phosphate which are potential therapeutic pathway for AA.¹² Thus, integrated network pharmacology and metabolomics Analysis may provide us an in-depth understanding for SWP in treating AA.

Our study was the first to identify the combinational rules of SWP from molecular and systematic level by integrated network pharmacology and metabolomics analysis, along with pharmacology experiments, to elucidate its therapeutic mechanism for AA induced by chemotherapy drugs.

Materials and Methods

Equipment, Chemicals and Reagents

The SWP products were generously provided by Hunan Jiudian Pharmaceutical Co., Ltd. (Hunan, China). In order to obtain reliable experiment results, the preparation and quality control (QC) of SWP were monitored according to our previous research.⁶ 2-Chloro-L-phenylalanine, as internal standards for metabolomics analysis, was purchased from Shanghai HC Biotech Co., Ltd. (Shanghai, China) and Avanti (USA) respectively. Q-Exactive LC-MS/MS (Thermo Fisher Scientific) Acetonitrile, methanol, formic acid and LC-MS grade water were purchased from CNW Technologies GmbH (Düsseldorf, Germany).

Animal

Our tests adhere to the Chinese national laws and local guidelines. Animal experiment has been authorized by the Animal Ethics Committee at Hunan Academy of Chinese Medicine (No.20190030). Healthy Male Sprague Dawley (SD) rat (8 weeks old, weighing 180–220 g) were purchased from Hunan SJA Laboratory Animal Co., Ltd (SCXK 2016–0002). Before the experiment, 30 rats were randomly divided into 3 groups, 10 rats in each group: control group, model group,

and SWP group (SWP). During the experiment, all animals were access to food and water freely, with standard surroundings: 12 h light and shade cycle, 50–55% humidity and temperature at 20–22°C.

In this section, the model of aplastic anemia was established on the basis of previous study.⁶ The model group and SWP group were intraperitoneal injected with Cyclophosphamide (CTX) (Baxter International Co., Ltd., Illinois, USA) and 1-Acetyl-2-phenylhydrazine (APH) (Meilun Biotechnology Co., Ltd., Dalian, China), while the control group received an equal volume of phosphate-buffered saline. Additionally, the SWP group was orally administered 22.68g/kg/d SWP, whereas the control and model groups obtained an equal amount of distilled water, lasted for 14 days.

Peripheral Blood Routine and Histological Analysis

After 14 days, rats were sacrificed under anesthesia and blood sample was collected through the abdominal aorta. The peripheral blood (PB) routine test, including white blood cell count ($WBC/10^9 \cdot L^{-1}$), red blood cell count ($RBC/10^{12} \cdot L^{-1}$), hemoglobin ($HGB/g \cdot L^{-1}$), haematocrit ($HCT/\%$), and platelet count ($PLT/10^9 \cdot L^{-1}$), was applied to evaluate the quantity of blood cells and to diagnosis conditions of blood.¹³

HE staining of femur was also employed to evaluate the medullary hematopoiesis function and the changes of hematopoietic microenvironment.¹⁴ Specific methods are as follows: the fixed femur (decalcified in 5.5g EDTA-2K + 100 mL 4% paraformaldehyde for 20 days in 4°C prior to the following experiments) were embedded in paraffin, and sectioned at 5 mm followed by staining with hematoxylin/eosin. Olympus BH-2 light microscope was used to observe the stained sections of femur tissue (Tokyo, Japan).

Network Pharmacology Prediction

Compound Data Preparation and ADME Screening

Traditional Chinese Medicine Systems Pharmacology Database and Analysis Platform (TCMSP) database (<http://lsp.nwu.edu.cn/tcmsp.php>, Ver.2.3), and Bioinformatics Analysis Tool for Molecular mechanism of Traditional Chinese Medicine (BATMAN) (<http://bionet.ncpsb.org/batman-tcm/>, updated January 2016)^{15,16} were used to select all candidate compounds of four herbs in SWP. In order to obtain bioactive components contributing to its therapeutic effect, all selected ingredients should meet the principle of ADME: 1. Oral bioavailability (OB) $\geq 30\%$, 2. Drug-likeness (DL) ≥ 0.18 .¹⁷ In addition, a widely scale data-mining strategy was adopted to replenish some bioactive ingredients, while those with poor pharmacological properties and bad drug ability compounds were removed.¹⁸

Targets Fishing and Network Construction

PharmMapper server (<http://lilab-ecust.cn/pharmmapper/>, updated April 10, 2019) was employed to discover the potential targets of SWP bioactive components.¹⁹ We gathered the AA-related targets from following database under the operating condition of “aplastic anemia” and “Homo sapiens”: ①GeneCards (<https://www.genecards.org/>, Ver. 5.0),²⁰ ②DisGeNET (<https://www.disgenet.org/>, Ver. 6.0),²¹ ③OMIM (<http://www.omim.org/>, updated Jun 27, 2017)²² ④TTD (<http://db.idrblab.org/ttd/>, updated Jan 8, 2020).²³ Herb-Compounds-Target-Pathway network of SWP was displayed by a visualization tool named Cytoscape (ver.3.7.0).²⁴ The STRING (<https://string-db.org/>, ver. 11.0) database was employed to predict the protein-protein interaction (PPI) in SWP for treating AA, and the operating conditions were “Homo sapiens” and correlation ≥ 0.7 .

GO and KEGG Enrichment Analysis for Targets

To investigate the potential biological pathways and critical targets, our study analyzed the PPI targets with Kyoto Encyclopedia of Genes and Genomes (KEGG), Gene Ontology (GO), and TRRUST (<https://www.grnpedia.org/trrust/>, ver.2).²⁵ The terms of GO or KEGG with p-value ≤ 0.05 were finally screened out for the research.

Metabolomics Analysis

Collection and Preparation of Serum Sample

The following methods were employed to prepare serum samples: 100 μ L aliquot of serum sample were taken from the -80°C refrigerator, thawed at 4°C for 30 minutes. To remove the protein in the sample, 10 μ L internal standard (0.3 mg/mL 2-chloro-L-phenylalanine) was dispersed in 300 μ L ice-cold mixture contained methanol and acetonitrile (2/1, v/v).

Then they were vortexed for one minute. Subsequently, the mixtures were handled with concentration under 13,000 rpm and 4 °C for 15 min. 400 µL of the clear supernatant was evaporated, reconstituted with 200 µL of 20% methanol, vortexed for 30s, and sonicated for 2 min. After centrifugation for 10 minutes (13,000 rpm, 4 °C), the supernatant was filtered through a 0.22 µm microfilter and transferred to LC vial. Finally, 10 µL of the supernatant was taken for LC-MS test. Equal volume samples from each group were mixed as Quality Control (QC) in our experiment. Aim to ensure the stability of the samples, the above samples were stored at 4 °C during the LC/MS experiment.

UPLC-Q-TOF/MS Analysis

An ACQUITY UPLC BEH C18 column (100 mm×2.1 mm, 1.7 µm, Waters, USA) were used for non-targeted metabolites' study to analyze the metabolic profiling under both positive and negative ESI ion modes. Water (containing 0.1% formic acid, v/v) (A) and methanol (B) formed the gradient elution, which procedure was optimized as follows: 0.01 min, 5% B; 1.5 min, 5% B; 3 min, 30% B; 7 min, 60% B; 9min, 90% B; 11 min, 100% B; 12 min, 100% B; 15 min, 5% B. The total procedure time was 15 min, the injection volume was 10 µL, the flow rate was 0.35 mL/min, and the column temperature was 45 °C. The following are the instrument parameters for this experiment: 320°C (+) and 320 °C (–) for ion source temperature; 3500 V (+) and 3100 V (–) for ion spray voltage; 30 PSI for curtain gas; 60–900 (+) and 60–900 (–) for mass scan; 30 eV for collision energy.

Identification and Quantitative Analysis

In the study, progenesis QI software (Waters Corporation, Milford, USA) was employed to perform standardized preprocessing of metabolomics data.²⁶ Subsequently, the acceptable ranges of Precursor, fragment and retention time are set as 5 ppm, 10 ppm and 0.02 min, respectively. In order to obtain reliable peak information, we exclude the interference of isotopes, internal standard and noise, and limit the minimum intensity of chromatographic peak to 15% of the base peak intensity. The peaks will be eliminated when their ion intensity equal to 0 exists in more than 60% of samples. The retention time, m/z and MS/MS information are used to automatically match the metabolite information of human metabolite database (HMDB), lipid maps (v2.3) and metlin database to identify the chromatographic peak. Finally, the endogenous metabolites with $P < 0.05$ were considered as the differential metabolites to distinguish SWP, model and control group after Student's test.

Target Verification of SWP in Treating AA

Virtual Docking

To decrease the complexity and improve the accuracy of the constituent-target network, Molecular Operating Environment (MOE 2015.10 software) was further employed in our study to validate the interaction between compounds and critical targets, according to previous studies.¹⁷

Elisa

Serum was obtained from the supernatant of blood sample after centrifugation at 4 °C. The levels of serum SPHK-1 (NO. 1229A15), PLD1 (NO. 1228A11), and PLD2 (NO. 1228A09) were monitored by ELISA kits according to the instructions of the manufacturer. All of the ELISA kits were purchased from ZCIBIO Technology Co., Ltd. (Shanghai, China).

Western Blot Analysis

Bone marrow cells (BMCs) were obtained for Western blot (WB) analysis. BMCs were washed out from rat femurs and tibiae using a 5 mL syringe with PBS (prechilled overnight at 4 °C). The suspension was then centrifuged at 3000 rpm under 4 °C for 15 min. The precipitate was collected, quenched in liquid nitrogen and stored at - 80 °C until analysis. WB analysis was performed as accordance with previous report.²⁷ In brief, BMCs sample were homogenized on ice in RIPA lysis buffer (Beyotime Biotechnology, China). After the above mixture was centrifuged, the supernatant was collected. Membranes were blotted with primary antibodies, anti-rat p-STAT1 (1:500 dilution), anti-rat GRB2 (1:1000 dilution) or anti-rat GSPT1 (1:1000 dilution), overnight at 4°C. Then incubated with horseradish peroxidase bound secondary antibody for 2 hours. Antibodies p-STAT1 (NO. YP0249), and GSPT1 (NO. YT1619) were obtained from

ImmunoWay Biotechnology Company (USA). Antibodies GRB2 (NO. ba32111) were purchased from Abcam (UK). Immunoreactive proteins were detected by ELX800 and quantified by ClinxChemiScope 6000 System.

Multivariate Statistical and Pathway Analysis

SPSS 23.0 software was used to analyze the experimental data. An analysis of variance (ANOVA) is performed to obtain statistical significance for comparisons between multiple parameters. The LSD test is performed under the assumption of equal variances; otherwise, Dunnett's T3 test is carried out to data with unequal variances. Statistical significance is established at $P < 0.05$ or $P < 0.01$. We tested the normality of the data. If the data fit the normal distribution, we did homogeneity analysis of variance, otherwise we did Kruskal–Wallis test and Dunn's test. Normally distributed data are displayed by $\bar{X} \pm SD$ or $\bar{X} \pm SEM$, while skewed data are presented as median (min-max). According to our previous study, random forest and SIMCA software package (version 14.0, Umetrics, Umeå, Sweden) was used to observe the metabolic profiles and differential metabolites in different experimental groups under positive and negative mode. As described in previous studies, differential metabolites were sent to Metaboanalyst 4.0 for pathway enrichment analysis and pathway topological analysis.²⁸

Results and Discussion

Therapeutic Effect of Siwu Paste on AA Induced by CTX + APH

The results of peripheral blood (PB) and Histological examination indicated that we not only successfully established the aplastic anemia model, but also proved that SWP at the dose of this study had a positive effect on AA. Contrasted with control group, the level of WBC, RBC, HCT and PLT in AA model group was reduced obviously ($P < 0.01$). The above indices in SWP increased significantly compared with model group ($P < 0.05$, $P < 0.01$), suggesting that treatment of SWP could relieve the blood deficiency in AA rats. The details are displayed in [Figure 1A](#) and [Figure S1](#).

HE staining clearly shown the structure of periosteum, marrow cavity and cartilage tissue in control group, and abundant cellular components (granulocytes, megakaryocytes, nucleated cells, etc.) were observed in the medullary cavity. However, AA rats had serious medullary cavity injury, including edema of vascular fibrosis and significant fibrosis. After the treatment of SWP, the pathological condition of femur was improved significantly. The myelofibrosis, medullary cavity edema and fat cells were inhibited efficiently in SWP group. It was also observed that the proliferation of nucleated cells increased actively, and the number of erythrocytes in parenchyma vessels increased ([Figure 1B](#)). Overall, all the investigated parameters were changed significantly in AA rats, but they were restored by the SWP treatments.

The pharmacological study displayed the improving anemia and recovering hematopoietic functions effects of SWP treatment on AA animals, that were conformed to previous research.^{6,7} It suggests that SWP may be an alternative manner for AA induced by CTX + APH.

Network Pharmacology Analysis

Identification of Siwu Paste's Ingredients and Target Genes

To explore its specific mechanism of anti-anemia, network pharmacology analysis was performed. 230 ingredients were identified in SWP, containing 88 in *Angelicae Sinensis* Radix, 40 in *Rehmanniae radix* preparata, 81 in *Ligusticum chuanxiong* Hort., and 41 in *Cynanchum otophyllum* Schneid., and some repeating compounds were removed ([Table S1](#)). 19 active ingredients were screened from above library by ADEM criteria. According to the literature, eight compounds (Ferulic Acid, vanillin, senkyunolide-C, senkyunolide-D, senkyunolide-E, senkyunolide-A, cis-ligustilide, and senkyunolide-B) were considered to have therapeutic potential for AA, so even if they are below the standard, they are still selected for further study.^{8,9} [Table 1](#) provides detailed information on 27 potentially bioactive ingredients. 27 components were imported into the Pharmmapper database in SDF format for target prediction, and their norm fitting values were used for sorting. A total of 317 targets were screened out from the top 100 of each compound. Matching 317 targets with the AA-related targets acquired from GeneCards, DisGeNET, OMIM, and TTD, our study finally identified 64 common targets which considered as the potential gene for SWP in treating AA ([Table 2](#), [Figure 2A](#)).

Network Construction and Enrichment Analysis

Protein-Protein (PPI) interaction, GO and KEGG analysis were performed in 64 common targets to investigate target function and the potential mechanism of SWP on AA. A view of PPI network is displayed in Figure 2B. In this network, 7 nodes (containing ALB, AKT1, MAPK1, CASP3, HRAS, CAT, IL-2) with the value of degree > 20, were regarded as potential hub target for SWP to ameliorate the hematopoiesis disorder caused by AA.

As results shown in GO enrichment (Figure 2C), the top 4 enriched terms are positive regulation of biological process (GO:0048518), cellular protein metabolic process (GO:0044267), regulation of metabolic process (GO:0019222), and regulation of catalytic activity (GO:0050790), all of which belonged to Biological Process. Extracellular vesicle (GO:1903561), vesicle (GO:0031982), and cytosol (GO:0005829) with gene number > 7 belong to terms of GO cellular component. The terms of GO molecular functions mainly included catalytic activity (GO:0003824) and transferase activity, transferring phosphorus-containing groups (GO:0016772). Further TRRUST analysis demonstrates that the 64 targets were primarily regulated by Sp1 transcription factor (SP1, TRR00641), v-rel reticuloendotheliosis viral oncogene homolog A (avian) (RELA, TRR00575), nuclear factor of kappa light polypeptide gene enhancer in B-cells 1 (NF- κ B1, TRR00452), and jun proto-oncogene (JUN, TRR00323). Those results indicated that SWP may be mainly involved in regulation of metabolic and protein on treating AA.

In our research, there are 12 KEGG pathway ($P < 0.05$). The top 3 terms are FoxO signaling pathway (map04068), MAPK signaling pathway (map04010), Ras signaling pathway (map04014) which play an important role in the occurrence and development of AA (Figure 2D). A map of the “Herb-Compound-target-pathway” (including 71 nodes and 354 edges) based on KEGG analysis were established to investigate the mechanism of SWP on AA (Figure 2D). In

Figure 1 Therapeutic effect of Siwu Paste on Aplastic Anemia rats. (A) Effects of Siwu paste on peripheral blood routine of Aplastic Anemia Model Rats ^{*} $P < 0.05$, ^{**} $P < 0.01$ vs control group; [#] $P < 0.05$, ^{###} $P < 0.01$ vs model group ($n=7-10$). this network, DG was considered as a principal drug herb for regulating the most multiple compounds, which meet the TCM principles that DG is the sovereign drug in SWP. Moreover, we found that Mitogen-activated protein kinase 1 (MAPK1), RAC-alpha serine/threonine-protein kinase (AKT1), Glutathione S-transferase P (GSTP1), signal transducer and activator of transcription 1-alpha/beta (STAT1), growth factor receptor-bound protein 2 (GRB2) with higher degree also act critical targets for regulating or participating in multiple herbs or signaling pathways. Take GRB2 for example, it involves in multiple pathways related to the blood system, such as FoxO signaling pathway, Phospholipase D signaling pathway (map04072), MAPK signaling pathway, Ras signaling pathway.

GRB2, which links IL3 signaling to the ERK/MAPK proliferative pathway, has been reported to play important functions during the HSPC proliferation, survival and expansion.²⁹ STAT1 plays an important role in the regulation of erythropoiesis. Studies have shown that STAT1 deficiency leads to increased red blood cell apoptosis.³⁰ As a stem cell factor (SCF) receptor gene, KIT play a key role in regulating the growth, survival, and differentiation of erythroid progenitors alone, as well as a synergistic effect with erythropoietin (EPO).^{31,32} Ratajczak et al, demonstrated that the growth of hematopoietic colony would be inhibited by more than 30%, when the mRNA expression of KIT was blocked in bone marrow mononuclear cells (MNC).³³ Analysis of miRNA differential gene expression in bone marrow revealed that Ras signaling pathways and Rap1 signaling pathway were the most significantly altered pathways between AA patients and healthy controls.³⁴ The damage of aplastic anemia to bone marrow, HSPC and metabolism is partly due to antigen mediated immune response, which eventually leads to increased oxidative stress or inflammatory response.^{35–38} It has been recently reported that FoxO signaling-mediated autophagy and regulation of mitochondrial activity are necessary for maintenance of hematopoiesis homeostasis in HSPC metabolic.^{39–41} Our results suggest that promoting erythropoiesis may be an effective strategy for SWP in the treatment of AA.

Those results provide that the herbal combination may have a great range of possible molecular targets than each individual herb, which might help to explain the synergistic of SWP effects in treatment of AA.¹⁷

Metabolic Profiles Analysis

Identification of Differential Metabolites and Multivariate Data Analysis

LC-MS was used to identify endogenous serum metabolic profile between control, model, and SWP group (Figure S2). It can be clearly seen from the random forest method under positive and negative ion modes that the above three groups have been completely separated (Figure 3A). Compared with model group, SWP were closer to control group, as well as the latter one had the trend of regression to the control group. This part indicated that our SWP have the positive regulation on AA. Meanwhile, the QC group was clustered together tightly. It indicated that our metabolic profile is stable and reliable.

In addition, the differences between each two groups were analyzed by orthogonal partial least square-discriminate analysis (OPLS-DA), and the metabolic characteristics of different groups were visualized by SIMCA. In positive (Figure 3B) and negative (Figure 3C) ion modes, there was significant separation between each two groups. If the

metabolite meets the conditions of $VIP > 1$ and $P < 0.05$, it will be selected as a potential biomarker. Based on positive ions mode, there are 111 (93 up-/18 down-regulation) and 77 (45 up-/32 down-regulation) biomarkers identified respectively between control and model, and model and SWP. Analogously, 40 (28 up-/12 down-regulation) and 28 (3 up-/25 down-regulation) biomarkers were separately identified under negative ion mode in above mentioned groups (Figure 4, Table S2).

Metabolic Pathway Analysis

A total of 106 differential metabolites regulated by SWP were further analyzed at Metaboanalyst 4.0 to reveal their functional and metabolic characteristics. 17 metabolic pathways were enriched in our research (Table S3, Figure S3).

Figure 3 (A): Random forest pattern recognition analysis of global serum metabolic profile between the control group, model group, and Siwu Paste group in positive and negative-ion modes. OPLS-DA score plots between the above three groups in positive (B) and negative-ion modes (C), respectively (n=7).

According to the impact value > 0.1 , the top six metabolic pathways, which mainly enriched to lipid metabolism, amino acid, metabolism of terpenoids and polyketides, were obtained (Figure 5). Riboflavin and retinal were involved in Riboflavin metabolism (map00740, impact = 0.5) and Retinol metabolism (map00830, impact = 0.242) respectively. Sphingolipid metabolism (map00600, impact = 0.199) regulated by sphinganine, sphingosine, SM (d18:0/16:1(9Z)), and PE (16:1 (9Z)/P-18:1 (11Z)). Glycerophosphocholine, PC (20:4 (5Z,8Z,11Z,14Z)/P-16:0), PE (16:1 (9Z)/P-18:1 (11Z)), choline, LysoPC (17:0), and LysoPC (24:1 (25Z)) were metabolite nodes in the process of Glycerophospholipid metabolism (map00564, impact = 0.168). PC (20:4 (5Z,8Z,11Z,14Z)/P-16:0) and 15(S)-HPETE were charged in Arachidonic acid metabolism (map00590, impact = 0.1). Niacinamide was participated in the Nicotinate and nicotinamide metabolism (map00760, impact = 0.194). The regulation of SWP on the above 12 metabolites is regarded as a potential biomarker for SWP to reduce AA metabolic disorder (Table 3).

Study testified that Nicotinamide Riboside (NR) and Niacinamide, as nicotinamide adenine dinucleotide (NAD⁺) dietary supplements, recovery hematopoiesis function in mice suffering from hematological failure through reduced mitochondrial activity within HSPC.^{42–45} Though products of lipoxygenase in arachidonic acid metabolism are regarded as typical pro-inflammatory, recently study has been proved that 15-HPETE exhibit anti-inflammatory activity by destabilizing TNFmRNA.^{46,47} However, abnormal elevation of the membrane-located 15(S)-HPETE can trigger greater levels of oxidative damage to the polyunsaturated fatty acid side-chains, which finally induces the loss of erythrocyte membranes integrity.⁴⁸ In this study, the serum level of Nicotinamide Riboside, Niacinamide and 15(s)-HPETE in AA model group was significantly higher than that in control group, whereas the levels of LysoPC (17:0), LysoPC (24:1 (25Z) and PE (16:1 (9Z)/ P-18:1 (11Z)) were decreased markedly ($P < 0.05$). After SWP treatment, the above indexes were significantly restored ($P < 0.05$). Phosphatidylethanolamine (PE) regarded as a potent anti-inflammatory lipid.⁴⁹ It has been confirmed that an abundant of lyso-phosphatidylcholine (LPC) such as LysoPC (17:0) and LysoPC (24:1 (25Z)

Figure 4 Comparison of differentially expressed metabolites levels between control group, mode group and Siwu Paste group in positive (A) and negative-ion (B) modes.

in plasma, contributes to driving the activation of inflammatory responses.⁵⁰ We speculate that SWP may suppress the inflammation and oxidative damage by restoring the level of PE and LPC and balancing the abnormally increased 15(s)-HPETE under the AA. SWP may also promote the metabolism of Niacinamide for maintenance of adult HSC quiescence. It provides a better hematopoietic microenvironment for promoting hematopoiesis.

Our observations also illustrated that Glycerophospholipid metabolism and Sphingolipid metabolism including PE (16:1 (9Z)/P-18:1 (11Z), Glycerophosphocholine, Sphingosine, Sphinganine, and Sphingosine-1-phosphate, were related to the dysregulation of hematopoietic.^{51,52} Orsini's study provides evidence that sphingolipid was participated in TNF α -mediated modulation of TF/miR network and autophagy inhibition in HSPCs, affecting the formation of erythrocytes.⁵³ Sphinganine is a derivative of Sphingosine. The accumulation of them has been verified to suppresses Bcl-xL expression and downregulates Bcl-2 to enhance apoptosis, which accompanied by the strong inhibition of MAPK cascade.⁵⁴⁻⁵⁷ Whatmore, Thiet et al, study indicated that a significantly decrease in plasma S1P level in Major-facilitator superfamily transporter 2b (Mfsd2b) knockout mice would result in damaged membrane of erythrocyte and disordered PB.⁵⁸ They also found that sphingosine was highly accumulated when the secretion of S1P were block by knockout the Mfsd2b in red blood cell (RBC). On contrary, Sphingosine-1-phosphate (S1P), synthesized by phosphorylation of sphingosine in the presence of sphingosine kinase 1 (SphK1), was shown to have antiapoptotic properties.⁵⁴ Our and Wątek's research demonstrate that the levels of Sphingosine and Sphinganine were up-regulated significantly in the model with immune damage mediated by chemotherapeutic drugs, while the concentration of Sphingosine-1-phosphate (S1P) was significantly lower ($P < 0.05$).⁵⁹ After the treatment of SWP, the concentration of Sphingosine and Sphinganine was declined significantly compared with model ($P < 0.05$). The Sphingosine-1-phosphate has elevated tendency after treated with SWP with no significance.

Network Pharmacology and Metabolomics Integration Analysis

To further clarify the molecular mechanism and potential biological pathway of SWP for treatment of AA, we comprehensively analyzed the results of network pharmacology and metabonomics. Firstly, we searched the HMDB

The three-dimensional structures of proteins 4K2R, 3GUR and 4U2X were obtained by searching GSTP1, GRB2 and STAT1 from PDB protein database. All of the docking scores were less than -3.8 , which indicated that the proteins shown well binding activity (Table S4, Figure 7). The docking results are shown in Figure 7. It suggests that paeoniflorin, betulinic acid and senkyunolide-B may be involved in the regulation of GSTP1, STAT1 and GRB2 to support SWP in the treatment of AA caused by chemotherapy drugs. Western blot was also applied to further validate the results of virtual docking. In our study, compared with the control group, the protein expression of p-STAT1 ($p < 0.05$) and GSTP1 ($p < 0.01$) have been significant decreased by CTX-treatment, while the protein expression of GRB2 ($p < 0.01$) increased significantly (Figure 8 and Figure S4). After treated with SWP, p-STAT1 protein was significantly increased ($p < 0.05$) and GRB2 was obviously declined ($p < 0.05$) as compared to model group.

Compared with control group, model group developed higher serum levels of SPHK-1 ($p < 0.001$) and PLD1 ($p < 0.01$), while SWP obviously reduced above indexes ($p < 0.01, 0.05$) (Figure 8, Figure S5). Additionally, in contrast to control group, the serum levels of PLD2 were significantly decreased in model group ($p < 0.01$). After SWP intervention, the serum PLD2 were elevated as compared to model group ($p < 0.05$). Although the role of PLD

Figure 7 Virtual docking based on bioactive ingredients of Siwu Paste and therapeutic targets of Aplastic Anemia.

in AA remains unclear, our study suggests that PLD expression is disrupted in chemotherapy-induced AA and that SWP reverses this imbalance. In addition, it is partly consistent with the prediction of our networked pharmacology combined with metabolomics.

Figure 8 The experimental validation of Siwu Paste against Aplastic Anemia. The relative protein expression levels of GRB2 (A), p-STAT1 (B) and GSPT1 (C) were monitored by Western Blot. Serum SPHK-1, PLD1 and PLD2 levels were assessed by ELISA (D). The results of GSPT1 and PLD1 were expressed by median (min - max), while other data were expressed by mean $\pm$ SEM. * $P < 0.05$, ** $P < 0.01$, *** $P < 0.001$ vs control group; # $P < 0.05$, ## $P < 0.01$ vs model group.

Although we have examined the possible role of SWP in treating AA induced by CTX + APH, there are some limitations in the present study. Due to the limitation of the sample size, we cannot estimate the efficacy of SWP in large samples. Therefore, it is necessary to enlarge the sample size in future experiments. In addition, the potential targets and biological pathways predicted by network pharmacology combined with metabolomics methods need to be validated by more in vitro experiments. Targeting lipid metabolism is also the direction we need to work on in the next step.

Conclusion

In summary, our research confirmed the positive effect of SWP on aplastic anemia (AA), and enriched the possible pathway of SWP via network pharmacology and metabolomics analysis. In the component-target and PPI network, we identified 27 active compounds from SWP and 64 common proteins associated with AA. Furthermore, MAPK1, CASP3, STAT1, GRB2 and KIT were identified as the hub targets for SWP in treating AA. Metabolomics was employed to characterize the metabolic profiles of APH together with CTX-induced AA rats, attending to identified the endogenous markers that drive molecular mechanisms. SWP improved inflammation and oxidative damage of hematopoietic microenvironment predominantly by significantly down-regulated the elevated levels of 15(s)-HPETE, as well as dramatically up-regulated the levels of LysoPC (17:0), LysoPC (24:1 (25Z)) and PE (16:1 (9Z)/P-18:1 (11Z)). Most importantly, SWP effected hematopoietic by declined the accumulation of Niacinamide, Sphingosine and Sphinganine. The alter of these metabolites mainly involve in Sphingolipid metabolism, Glycerophospholipid metabolism, Arachidonic acid metabolism, Nicotinate and nicotinamide metabolism. Although we have examined the possible role of SWP in treating AA, there are some limitations in the present study. Further vitro and vivo experimental validation will be involved in our next step study.

Drug Design, Development and Therapy

Dovepress

Publish your work in this journal

Drug Design, Development and Therapy is an international, peer-reviewed open-access journal that spans the spectrum of drug design and development through to clinical applications. Clinical outcomes, patient safety, and programs for the development and effective, safe, and sustained use of medicines are a feature of the journal, which has also been accepted for indexing on PubMed Central. The manuscript management system is completely online and includes a very quick and fair peer-review system, which is all easy to use. Visit <http://www.dovepress.com/testimonials.php> to read real quotes from published authors.

Submit your manuscript here: <https://www.dovepress.com/drug-design-development-and-therapy-journal>
