**Background:** Cancer treatments are being continually developed. Increasingly more effective and better-targeted treatments are available. As treatment has developed, the outcomes have improved.

**Purpose:** In this work, polyethylene glycol (PEG), layered double hydroxide (LDH) and 5-fluorouracil (5-FU) were used as a stabilizing agent, a carrier and an anticancer active agent, respectively.

**Characterization and methods:** Magnetite nanoparticles (Fe<sub>3</sub>O<sub>4</sub>) coated with polyethylene glycol (PEG) and co-coated with 5-fluorouracil/Mg/Al- or Zn/Al-layered double hydroxide were synthesized by co-precipitation technique. Structural, magnetic properties, particle shape, particle size and drug loading percentage of the magnetic nanoparticles were investigated by XRD, TGA, FTIR, DLS, FESEM, TEM, VSM, UV-vis spectroscopy and HPLC techniques.

**Results:** XRD, TGA and FTIR studies confirmed the formation of Fe<sub>3</sub>O<sub>4</sub> phase and the presence of iron oxide nanoparticles, polyethylene glycol, LDH and the drug for all the synthesized samples. The size of the nanoparticles co-coated with Mg/Al-LDH is about 27 nm compared to 40 nm when they were co-coated with Zn/Al-LDH, with both showings near uniform spherical shape. The iron oxide nanoparticles retain their superparamagnetic property when they were coated with polyethylene glycol, polyethylene glycol co-coated with Mg/Al-LDH and polyethylene glycol co-coated with Zn/Al-LDH with magnetic saturation value of 56, 40 and 27 emu/g, respectively. The cytotoxicity study reveals that the anticancer nanodelivery system has better anticancer activity than the free drug, 5-FU against liver cancer HepG2 cells and at the same time, it was found to be less toxic to the normal fibroblast 3T3 cells.

**Conclusion:** These are unique core-shell nanoparticles synthesized with the presence of multiple functionalities are hoped can be used as a multifunctional nanocarrier with the capability of targeted delivery using an external magnetic field and can also be exploited as hyperthermia for cancer cells in addition to the chemotherapy property.

**Keywords:** nano drug delivery, layered double hydroxide, core-shell nanoparticles, iron oxide nanoparticles, 5-fluorouracil

## Introduction

Cancer is caused by cells mutation in the human body and the mutated cells reproduce at a higher rate than the healthy cells.<sup>1-3</sup> There is a variety of approaches to control cancer disease including surgery,<sup>4,5</sup> hormone therapy, immunotherapy<sup>6-8</sup> and radiation therapy or a combination thereof.<sup>9</sup> However, these common therapies posed some disadvantages such as patient inconvenience (pain), the disappearance of healthy cells, long-term treatment and high expenditure.<sup>9,10</sup> One of the ways to

treat cancer or its temporary relief is to use certain medications known as chemotherapy.<sup>10,11</sup>

The chemotherapy is to specifically eliminate or destroy cancer cells by chemical drugs without damaging adjacent and healthy tissues.<sup>12,13</sup> The development of targeted drug delivery methods using nanotechnology platform through the use of nanoparticles has emerged to help cancer diagnosis and treatment.<sup>4,14</sup> Magnetic nanoparticles have great potential for both cancer diagnosis and treatment.<sup>5,7,15</sup> They have been used as contrast factors in the magnetic resonance imaging (MRI) as well as the nanocarrier in modern drug delivery systems.<sup>16–18</sup> In recent years, the targeted transfer of chemotherapeutic agents to cancer cells by magnetic nanoparticles has been studied and researched by many scholars and have yielded valuable and desirable results.<sup>19</sup> Nanotechnology-based drug delivery systems (DDS) have dramatically improved drug therapies due to modification of drug properties,<sup>20–22</sup> increased drug bioavailability in the bloodstream,<sup>23</sup> reduced toxicity<sup>24</sup> and increased half-life of the drug.<sup>24–26</sup> All of these features were achieved through the improved of drugs delivery by magnetic nanoparticles with its unique characteristics as drug carriers.<sup>21,27</sup>

Recently, much attention has been paid to the use of nanoparticles as carriers for drug delivery.<sup>14,28,29</sup> Nanoparticle carriers can improve drug performance and reduce side effects.<sup>30,31</sup> In the manufacture of the nanoparticles, various materials to transfer drugs such as polymers,<sup>10,32–35</sup> metals, lipids, layered double hydroxides, magnetic NPs decorated lipophilic dyes (magnetoliposomes), chitosan nanoparticles, gold and silver nanoparticles,<sup>2,36–45</sup> etc. were used as drug carriers with different shapes and sizes, as well as the fabrication methods.<sup>46–49</sup>

Magnetic nanoparticles as core are of great importance in DDS due to their inherent magnetism and ability to selectively attached to the molecules or tissue specific and allow transportation to a targeted location under an external magnetic field.<sup>48,49</sup> In addition, magnetic nanoparticles have been widely used owing to their superior properties such as targeted drug delivery and low side effects.<sup>50</sup> Size and surface properties of magnetic nanoparticles play a significant role in determining their ability to cross the cancer cell membrane.<sup>51</sup> Additionally, a sufficient magnetic gradient field is required to direct the nanoparticle to the target.<sup>52</sup> For magnetic targeting, the therapeutic agent is embedded into the magnetic nanoparticles, introduced into the body and directed to the target area under magnetic field. Magnetic nanoparticles release the drug through simple penetration or through

mechanisms that require enzymatic activity or temperature or pH changes. One of the reasons for the use of magnetic nanoparticles is their biocompatibility and toxicity. Previous studies have shown that these nanoparticles exhibit low toxicity because of the concentration required for drug delivery purposes is often lower than the levels that causing poisoning.<sup>53–57</sup>

In this study, we develop superparamagnetic core-shell nanoparticles based on Fe<sub>3</sub>O<sub>4</sub> core, coated not only with polymer but also co-coating with LDHs. Fe<sub>3</sub>O<sub>4</sub> as the core is coated with PEG-Mg/Al-LDH or PEG-Zn/Al-LDH, as the shells followed by loading with 5- fluorouracil as an anti-cancer drug for the liver.

## Materials and methods

### Materials

Deionized water (18.2 MΩcm<sup>-1</sup>) was used in all the experiments. Ferrous chloride tetrahydrate (FeCl<sub>2</sub>·4H<sub>2</sub>O) and ferric chloride hexahydrate (FeCl<sub>3</sub>·6H<sub>2</sub>O) with 99% purity were procured from Merck (Germany). Polyethylene glycol, with 6000 molecular mass was purchased from Acros Organics (USA). Ammonia solution (25%) was acquired from Scharlau (Barcelona, Spain). Aluminum nitrate (Al (NO<sub>3</sub>)<sub>3</sub>·9H<sub>2</sub>O ≥98.5%), zinc nitrate hexahydrate Zn (NO<sub>3</sub>)<sub>2</sub>·6H<sub>2</sub>O with 98% purity and magnesium nitrate (Mg (NO<sub>3</sub>)<sub>2</sub>·6H<sub>2</sub>O ≥99%) were supplied by ChemAR (Kielce, Poland). 5-fluorouracil (C<sub>4</sub>H<sub>3</sub>FN<sub>2</sub>O<sub>2</sub>) is a liver anti-cancer drug with 98% purity was obtained from AKSci (CA, USA) and dimethyl sulfoxide ((CH<sub>3</sub>)<sub>2</sub>SO with 99% purity) was obtained from Sigma Aldrich (Germany) and they were used in this study.

### Methods

To prepare Fe<sub>3</sub>O<sub>4</sub> nanoparticles, a mixture of 2.4 g ferrous chloride tetrahydrate (FeCl<sub>2</sub>·4H<sub>2</sub>O), 0.9 g ferric chloride hexahydrate (FeCl<sub>3</sub>·6H<sub>2</sub>O) and 100 mL deionized water in the presence of 10 mL ammonium hydroxide (25% by mass) It was exposed to ultrasonic irradiation for 2 hrs. Afterward, the precipitates were washed 3 times, centrifuged and dispersed in 50 mL mixture of 2 g of polyethylene glycol (PEG) in deionized water. Thereafter, the synthesized nanoparticles were left in an autoclave at 150 °C for 20 hr. To eliminate the additional PEG which does not contribute to the coating process, the black precipitates were collected and washed. The coated iron oxide nanoparticles (FPEG) was added into 3 g of 5-fluorouracil, which was solvable in DMSO (dimethyl sulfoxide), and

the mixture was stirred for 24 hr. The final nanoparticles were re-dispersed in 50 mL deionized water and layered double hydroxide solution (Mg/Al) was added dropwise into the combination solution under strong stirring till the pH was decreased to 9–10.

The Mg/Al-layered double hydroxides (MLDH) nanocarrier was prepared by co-precipitation procedure. Briefly, the solution of magnesium and aluminum nitrates,  $\text{Mg}(\text{NO}_3)_2 \cdot 6\text{H}_2\text{O}$  and  $\text{Al}(\text{NO}_3)_3 \cdot 9\text{H}_2\text{O}$  were dissolved in 50 mL distilled water. At the same time, 75 mL NaOH (0.2 mol/L) was added dropwise with good stirring. Finally, the resulting core-shell nanoparticles were centrifuged at 5000 rpm, washed and dried in an oven at 40 °C. A similar process was done to synthesise magnetic nanoparticles with Zn/Al-layered double hydroxide (ZLDH).

## Characterization

In order to determine the crystal structure of the prepared samples, X-ray diffraction (a Shimadzu XRD 6000, Japan) was used in a range of 2–80° using the  $\text{CuK}\alpha$  radiation ( $\lambda = 1.5406 \text{ \AA}$ ) at 40 kV and 30 mA. The morphology, mean particle size and particle size distribution were examined by a transmission electron microscope (TEM, Hitachi H-7100, Tokyo, Japan) at an accelerating voltage of 100 kV and the particle size distribution was obtained by an image analysis software (UTHSCSA Image Tool V.6). The thermal decomposition of the core-shell nanoparticles with Mg/Al- and Zn/Al-LDH were determined by the thermogravimetric analysis (TGA/DTG) using a Mettler-Toledo instrument (Greifensee, Switzerland) from 20–1000 °C at a heating rate of 10 °C  $\text{min}^{-1}$ .

To investigate the particle size distribution of the samples, dynamic light scattering (a DLS, MALVERN, Nano S, UK) was used. The samples were diffused in methanol and exposed to ultrasonic irradiation for 1 h (40% power in 40 °C) prior to the measurement of the drug loading. Percentage of the drug loading of the samples was determined using the high-performance liquid chromatography (an HPLC, ALLIANCE, e2695, USA). Fourier transform infrared (FTIR) spectra were recorded in the range between 400–4000  $\text{cm}^{-1}$  on a Thermo Nicolet 6700 (AEM, Madison WI, USA) with 0.09  $\text{cm}^{-1}$  resolution, using the potassium bromide disk method.

To study the magnetic properties, a vibrating sample magnetometer (VSM, Lakeshore 7404, Westerville, OH, USA) was used. A field emission scanning electron microscope (FESEM, NOVA NANOSEM 230, California,

USA) was used to investigate the shape and morphology of the nanoparticles. A CHNSO (LECO, TruSpec, Stockport, UK) analyzer was used to determine the percentages of oxygen, nitrogen, hydrogen, sulphur and carbon compounds. The magnesium, zinc, aluminum and iron content of the nanoparticles was studied with a PerkinElmer spectrophotometer (Perkin Elmer, Wellesley, MA, USA) (Model Optima 8300) inductively coupled plasma atomic emission spectrometry (ICP-ES).

For TEM, VSM, SEM, XRD and TGA analyses, the samples were first dried in an oven at 40 °C for 24 hrs. To determine the particle size distribution, the sample in water was ultrasonicated using an ultrasonic bath. For the high-performance liquid chromatography and CHNSO analyses, first, the samples were diluted in methanol and PBS at pH 7.4 with the ratio of 1:1 and ultrasonicated before the measurement. For the FTIR study, the KBr technique was adopted and the FTIR spectra were obtained in the range of 4000–500  $\text{cm}^{-1}$ . Purification of the nanoparticles from excess polymer and drug before further characterization of the composition and loading was done by washing the sample 3 times with excess deionized water. We found that such a step was good enough to give a consistence result.

## Cell culture and MTT cell viability assays

Cell viability assay was conducted to analyze the toxicity level of the nanoparticle to cell lines. Two types of cells were used for the cytotoxicity assay; the healthy human fibroblast (3T3) and human hepatocellular carcinoma cells (HepG2) which were purchased from ATCC (Manassas, USA). Both cells were grown in the Roswell Park Memorial Institute (RPMI) of 1640 medium (Nacalai Tesque, Kyoto, Japan) supplemented with 10% fetal bovine albumin (Sigma-Aldrich, MO, USA), 1% antibiotics containing 10,000 units/mL penicillin and 10,000  $\mu\text{g}/\text{mL}$  streptomycin (Nacalai Tesque, Kyoto, Japan). Cells were maintained and incubated in humidified 5% carbon dioxide/95% room air at 37 °C. Cells layers were harvested using 0.25% trypsin/1mM-EDTA (Nacalai Tesque, Kyoto, Japan). This followed by seeded in a 96-well tissue culture plates at  $1.0 \times 10^4$  cells/well for 24 hrs in an incubator to attach and 90% confluence attained for treatment.

Methylthiazol tetrazolium (MTT)-based assay was carried out to determine the cell viability and cytotoxicity. Cells were treated with iron oxide (Fe), FPEG, FPEG-MLDH, FPEG-ZLDH (the nanocarriers), 5-fluorouracil (drug pure compound), FPEG-FU-MLDH and FPEG-FU-

ZLDH (nanoparticles), where stock solutions were prepared by dissolving the compound in 1:1 of dimethyl sulfoxide (0.1 %) and RPMI. Then, the mixture was further diluted in the same media to produce various final concentrations, ranging from 1.25 to 100  $\mu\text{g/mL}$ . Once the cells were attached to the respective wells after 24 hrs, the tested compounds were added until the final volume of 100  $\mu\text{L}$  well was obtained. After 72 hrs of incubation, 10  $\mu\text{L}$  of MTT solution (5 mg/mL in PBS) was added in each well and further incubated for 3 hrs before being aspirated. Then 100  $\mu\text{L}$  of dimethyl sulfoxide was added per well in the dark and room temperature in order to dissolve the purple formazan salt. The intensity of the purple formazan solution, which reflects cell growth was subsequently measured at a wavelength of 570 nm using a microplate reader (Biotek LE800, Winooski, Vermont, USA).

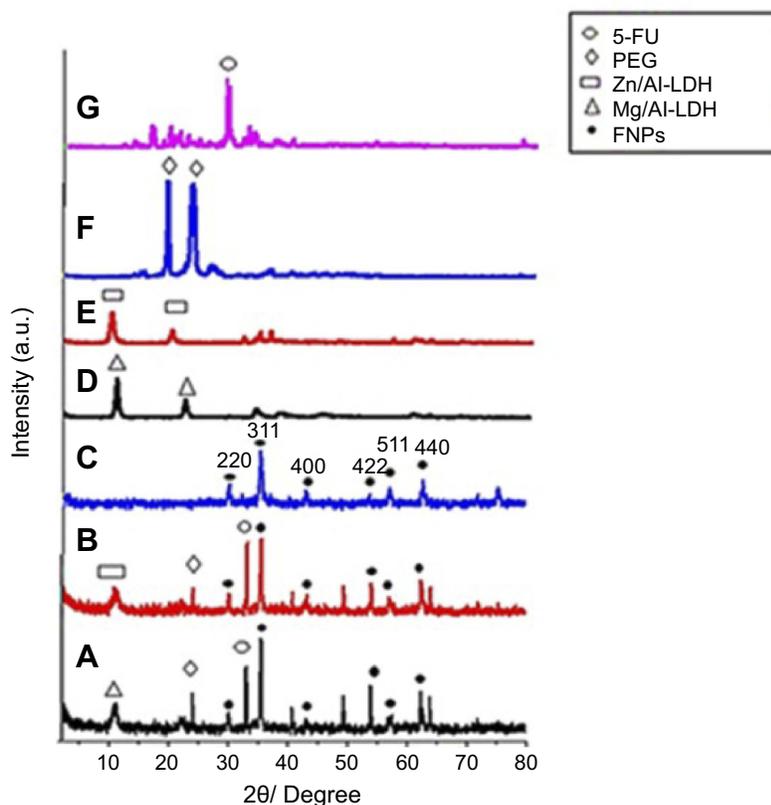

## Results and discussion

### X-ray diffraction

The diffraction planes of (003) and (006) at  $10.9^\circ$  and  $22.1^\circ$ , respectively were observed, indicating the characteristic peaks of pure Zn/Al-LDH, 2D-layered structure

(Figure 1E). In addition, the XRD pattern for MLDH with high intensity of (003), (006) and (009) reflections were observed at the  $2\theta$  positions of  $11.5^\circ$  and  $23.2^\circ$  and  $34.8^\circ$ , respectively (Figure 1D). Additionally, 6 characteristic peaks of iron oxide with a cubic inverted spinel structure were also observed at  $2\theta = 30.16^\circ$ ,  $35.95^\circ$ ,  $43.34^\circ$ ,  $54.17^\circ$ ,  $57.27^\circ$  and  $62.98^\circ$  (JCPDS No: 82-1533) (Figure 1C).<sup>30</sup> Pure PEG is represented by two main diffraction peaks of high intensity at  $19.3^\circ$  and  $23.50^\circ$  (Figure 1F).<sup>34,58</sup> The characteristic peak of 5-FU appeared at  $28.44^\circ$  (Figure 1G).<sup>59</sup> The XRD peaks of core-shell nanoparticles with MLDH and ZLDH nanocarriers are presented in Figure 1A and B, respectively.

Based on Figure 1, the XRD pattern is dominated by  $\text{Fe}_3\text{O}_4$  as shown by the reflections indicated for the  $\text{Fe}_3\text{O}_4$  phase. However, the presence of a small amount of  $\text{Fe}_2\text{O}_3$  cannot be ruled out. It was obvious that the coating process did not significantly change the dominated phase of  $\text{Fe}_3\text{O}_4$  nanoparticles. Furthermore, it can be seen that polyethylene glycol was coated onto the  $\text{Fe}_3\text{O}_4$  nanoparticles. Characteristic peaks related to the drug, 5-FU was also observed on both samples, indicating that the drug, 5-

**Figure 1** XRD patterns of (A) core-shell nanoparticles coated with Mg/Al-LDH, (B) core-shell nanoparticles coated with Zn/Al-LDH, (C) pure FNPs, (D) Mg/Al-LDH, (E) Zn/Al-LDH, (F) PEG, (G) 5-FU. The nanoparticles are composed of pure FNPs, PEG, 5-FU and Mg/Al-LDH (for A) or Zn/Al-LDH (for B).

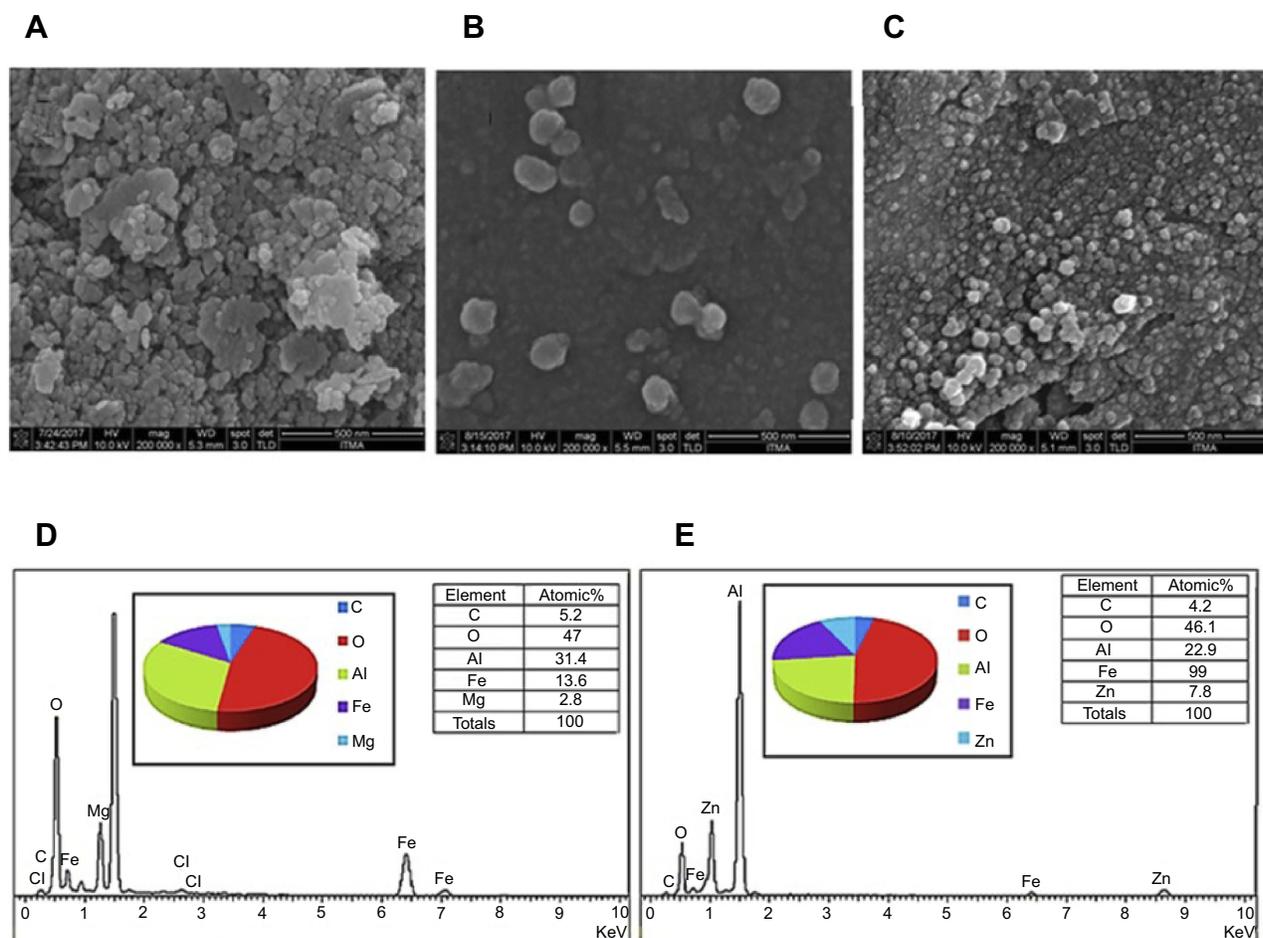

FU was also incorporated onto the nanoparticles. Furthermore, the peaks related to MLDH and ZLDH nano-carriers were also appeared in the synthesized samples, indicating that the nanoparticles were LDH-coated. The  $\text{Fe}_3\text{O}_4$ , PEG and 5-FU peaks can be still observed after the coating process with both LDHs, but the crystallization intensity was reduced. It is noteworthy that although the reflections for core-shell nanoparticles coated with Mg/Al-LDH or Zn/Al-LDH that are attributed to the various substances are not exactly identical to the peaks for the pure compounds; PEG and 5-FU together with Mg/Al-LDH or Zn/Al-LDH, respectively, the shifts are presumably due to the slight change in the chemical interactions of the compounds in the resulting nanoparticles.

## Morphology and particle size distribution

The size and particle size distribution of magnetic nanoparticles play a significance role in the drug delivery

system. Furthermore, for magnetic nanoparticles, their physical and chemical properties in aqueous environments like blood depend on their size. Therefore they often shipped as dry powders and dispersed in an aqueous environment for later use, and the later causes most of the particles to be agglomerated. Therefore their stability has to be evaluated by FESEM and DLS analyses.

As will be mentioned later, iron oxide particles are usually strongly agglomerated. In fact, when the particle size is reduced, their ratio of the surface to volume is increased and as a result, the weight of the particles also increased which leads to the formation of agglomerates. These agglomerates result from the aggregation of the small size of the synthesized particles. In this work, after the samples were prepared, their stability of the nanoparticles was compared. The results showed that sample b, which had been co-coated with Mg/Al-LDH, was found to be more stable than sample c.

**Figure 2** Field emission scanning electron micrograph (FESEM) of (A) FNPs, (B) the nanoparticles co-coated with Mg/Al-LDH, (C) the nanoparticles co-coated with Zn/Al-LDH and EDX spectra of (D) the nanoparticles co-coated with Mg/Al-LDH, (E) the nanoparticles co-coated with Zn/Al-LDH. \*The sample holder is made of aluminum, therefore resulting in a high percentage of aluminum, and therefore it is not reliable to indicate the aluminum content of the sample.

Figure 2 shows the field emission scanning electron micrographs (FESEM) of the iron oxide nanoparticles (Figure 2A), the nanoparticles co-coated with MLDH (Figure 2B) and the nanoparticles co-coated with ZLDH (Figure 2C) at magnifications of 200,000x. These images show that the nanoparticles of both samples are agglomerated, presumably during the time of the drying process. The degree of agglomeration was reduced as observed after the iron oxide nanoparticle was coated with PEG polymer, the LDHs and the drug. The FESEM images show that the surface of the particles is slightly spherical. However, the particle sizes of these nanoparticles, determined from SEM images and DLS are slightly larger than those reported by the TEM.

The compositional analyses of the nanoparticles with obtained from SEM-EDX study confirms the presence of all the compositional elements in the nanoparticles. The

data obtained from EDX study is presented in Figure 2. The table in Figure 2D and E indicate the atomic percentage of iron and oxygen in the synthesized nanoparticles, which is 13.6% and 47%, respectively for the nanoparticles co-coated with Mg/Al-LDH compared to 19% and 46.1%, respectively for the nanoparticles co-coated with Zn/Al-LDH. For PEG-coated FNPs and Mg/Al-LDH, the atomic percentages of carbon, magnesium and aluminum were found to be 5.2, 2.8 and 31.4%, respectively as shown in Figure 2D. For PEG and Zn/Al-LDH coated nanoparticles, the atomic percentages of carbon, zinc and aluminum were found to be 4.2, 7.8 and 22.9%, respectively (Figure 2E). The presence of PEG is evident from the appearance of the peak of carbon. The presence of zinc, magnesium and aluminum are resulting from the nanocarriers; MLDH and ZLDH used for the preparation process. The binding energies of iron for the whole core-

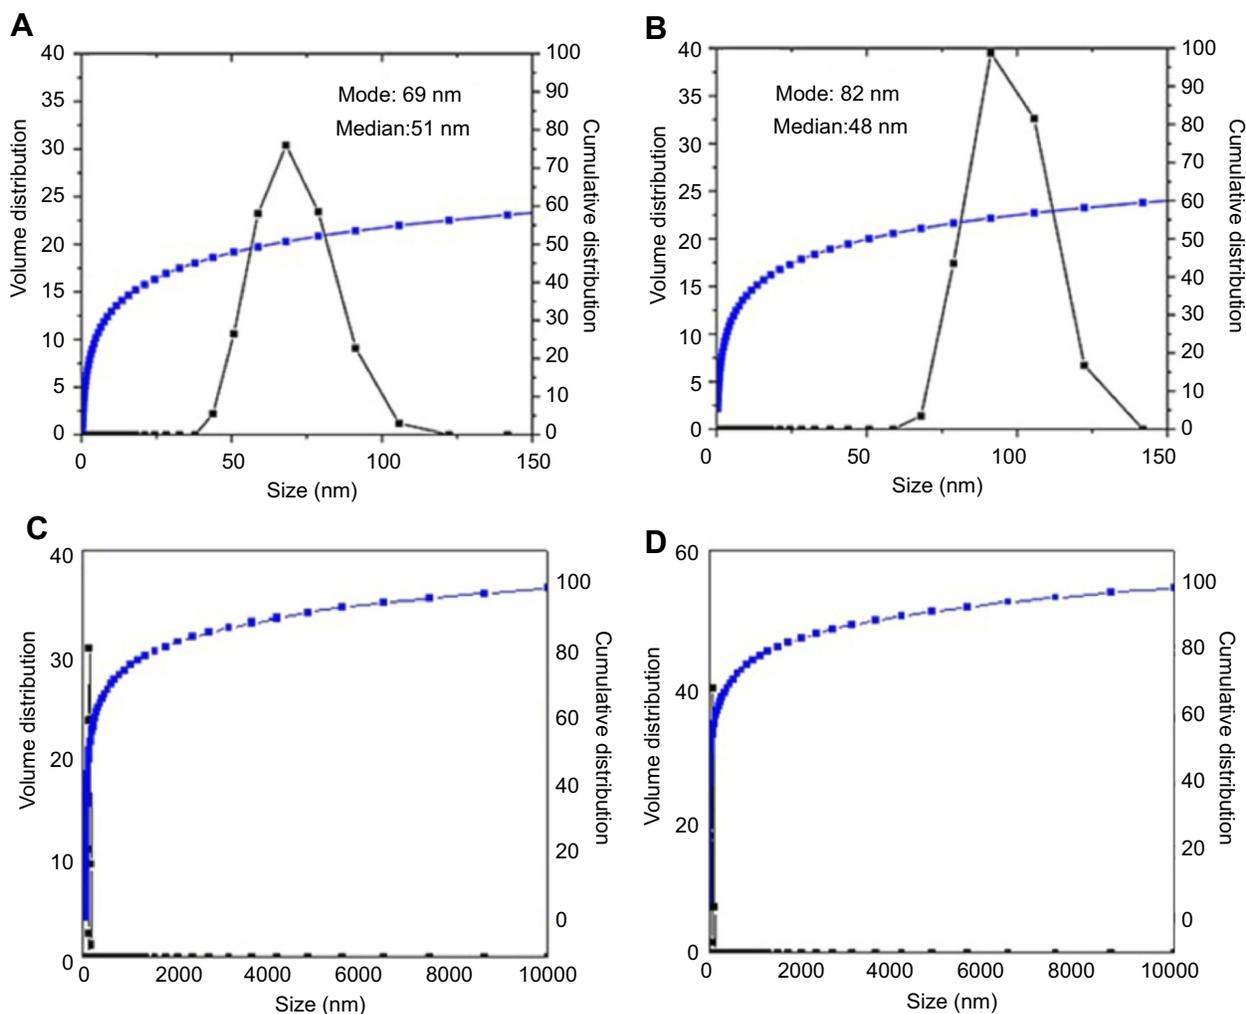

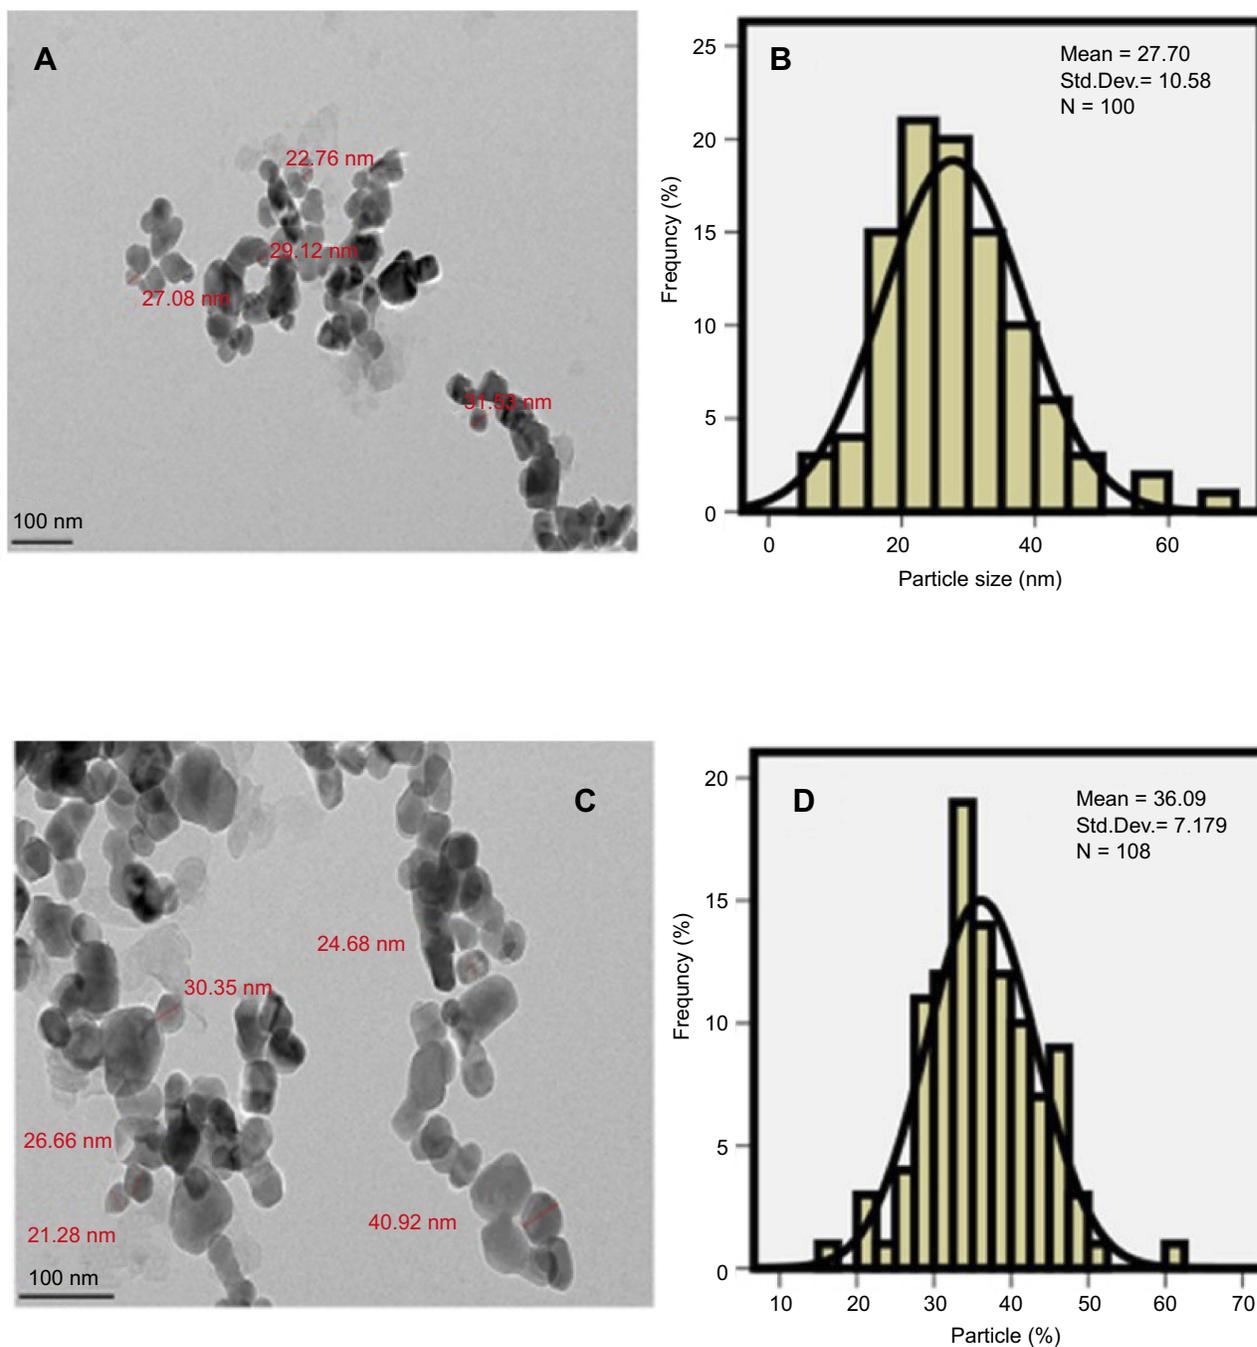

Figure 3 DLS particle size distribution of the nanoparticles co-coated with (A) Mg/Al-LDH, (B) Zn/Al-LDH and their 100% cumulative is given in C and D, respectively.

shell nanoparticles are presented by peaks observed at the energy values of 0.7 and 6.4 keV.<sup>37,38</sup>

The particle size distribution of the nanoparticles synthesized in this work was found to depend on the co-coated agents, MLDH and ZLDH, which was studied via dynamic light scattering (DLS) as revealed in Figure 3. The cumulative distribution frequency for the core-shell nanoparticles shows

a narrow size distribution in the range of 40–110 nm and the hydrodynamic diameter of 69 nm (Figure 3A). The nanoparticles co-coated with Zn/Al-LDH revealed a narrow size distribution, between 70–125 nm with the hydrodynamic particle size of 82 nm as revealed in Figure 3B. Their 100% cumulative distribution is given in Figure 3C and D for MLDH and ZLDH, respectively.

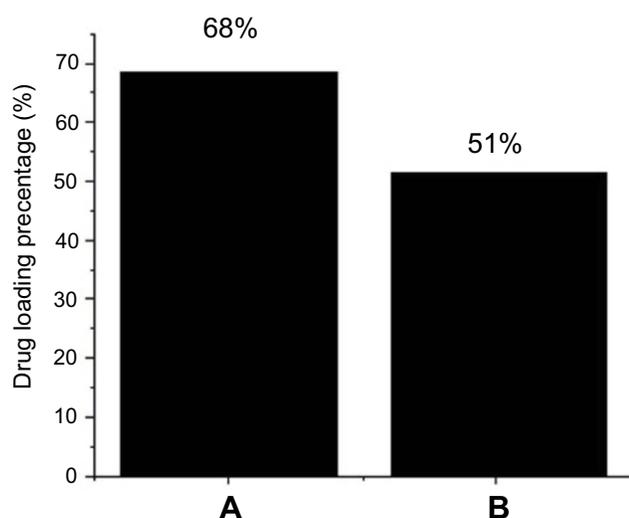

**Figure 4** Transmission electron micrographs for (A) the nanoparticles co-coated with Mg/Al-LDH (100 nm bar), (B) Their particle size distribution, (C) the nanoparticles co-coated with Zn/Al-LDH (100 nm bar), (D) their particle size distribution.

## Mean size and particle size distribution by TEM method

The nanoparticles size distribution is of great importance which also determines the degree of superparamagnetic properties and their retention time in the body. The size, uniformity, shape and the size distribution of the synthesized nanoparticles were studied by TEM (Figure 4A and C). The co-coated Mg/Al-LDH nanoparticles have the mean particle size of 28 nm with a narrow size distribution, compared to 40 nm for the co-coated Zn/Al-LDH nanoparticles as shown in Figure 4B and D). The size and size distribution of the nanoparticles were obtained by gauging of around 100 nanoparticles chosen randomly. It is clear that the synthesized core-shell nanoparticles were generally spherical shapes and fairly monodisperse.

It is worth noted that the core of the nanoparticles is composed of iron oxide nanoparticles (ION) coated with negatively charged drug and LDH nanocarrier. DLS gave the higher value of the particle size distribution due to the aggregation of the nanoparticles together to form larger particles as shown by FESEM study. On the other hand, HRTEM gave the actual size measurement of each of the nanoparticles in their non-agglomerated dried form. This is why the particles size distribution of the nanoparticles shows higher values when they were measured using DLS method compared to the HRTEM method.

**Figure 5** HPLC plot of (A) the nanoparticles co-coated with Mg/Al-LDH, (B) the nanoparticles co-coated with Zn/Al-LDH.

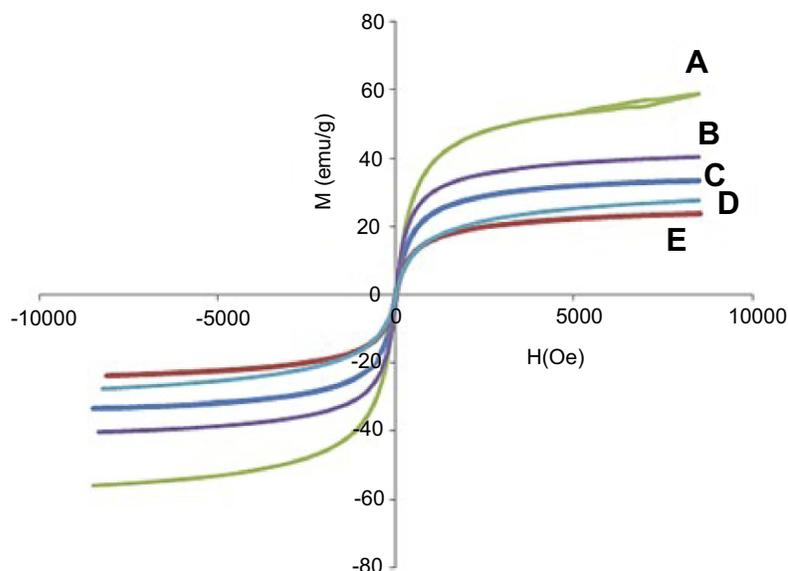

## Percentage loading of the drug by HPLC analysis

High-performance liquid chromatography (HPLC) was used for the quantification of the drug loading (Figure 5). The method developed by Zhu et al.<sup>60</sup> was used for 5-FU quantification with slight modification.<sup>61,62</sup> In brief, a mobile phase made up of methanol and 5 mole  $\text{KH}_2\text{PO}_4$  (pH 6.0) in a ratio of 4:96 v/v and the flow rate was set to 1 mL/minute. Agilent C18 column (3.9X150, 4.6  $\mu\text{m}$ ) was used with the column oven temperature of 30 °C and photodiode array detector (PDA) was used in a Waters HPLC 2695 separation module. Prior to sample analysis, standards of 5-FU; 25, 50, 100, 150 and 200 ppm and a calibration curve was formed with  $R^2$  of 0.99. The drug, 5-FU loading percentage of the core-shell nanoparticles using MLDH and ZLDH was found to be 68% and 51%, respectively. The LDHs alone have been reported to have lower drug loading in the literature and the higher loading may possibly attribute to the core-shell structure, and the presence of polymer provides many functional groups for more interaction with the drug molecules on the surface of the drug delivery systems.<sup>61–65</sup>

## Magnetic properties

Superparamagnetic properties are important in magnetic targeted drug delivery system. Hysteresis loops of naked iron oxide nanoparticles (Figure 6A),  $\text{Fe}_3\text{O}_4$  coated with PEG and co-coated with Mg/Al-LDH (Figure 6B) and  $\text{Fe}_3\text{O}_4$  co-coated with Zn/Al-LDH (Figure 6C) characterized by a vibrating sample magnetometer (VSM) at room temperature show they have superparamagnetic properties. The parameters in vibrating sample magnetometers (VSM) extracted from the values of saturation magnetization ( $M_s$ ), remnant magnetization ( $M_r$ ) and high coercivity ( $H_c$ ) are revealed in Table 1. The superparamagnetic materials show that they have high saturation magnetization and zero coercivity and remanence magnetization.<sup>66,67</sup>

The saturation magnetization of the prepared magnetic nanoparticles,  $\text{Fe}_3\text{O}_4$  was about 58 emu/g, slightly higher compared to 40 emu/g for  $\text{Fe}_3\text{O}_4$  coated with PEG and Mg/Al-LDH, and 27 emu/g for  $\text{Fe}_3\text{O}_4$  coated with PEG and Zn/Al-LDH. After  $\text{Fe}_3\text{O}_4$  was coated with PEG and co-coated with MLDH and ZLDH, the saturation magnetization was reduced which could be attributed to the coating materials on the surface of magnetic nanoparticles. This saturation magnetization was further reduced after the addition of the drug, due to the presence of another layer on the iron oxide nanoparticles (Figure 6D and E).

**Figure 6** Magnetization curves of (A) FNPs, (B) FPEG-Mg/Al-LDH, (C) FPEG-Zn/Al-LDH, (D) the nanoparticles co-coated with Mg/Al-LDH, (E) the nanoparticles co-coated with Zn/Al-LDH recorded at room temperature.

**Table I** Magnetic properties of the nanoparticles

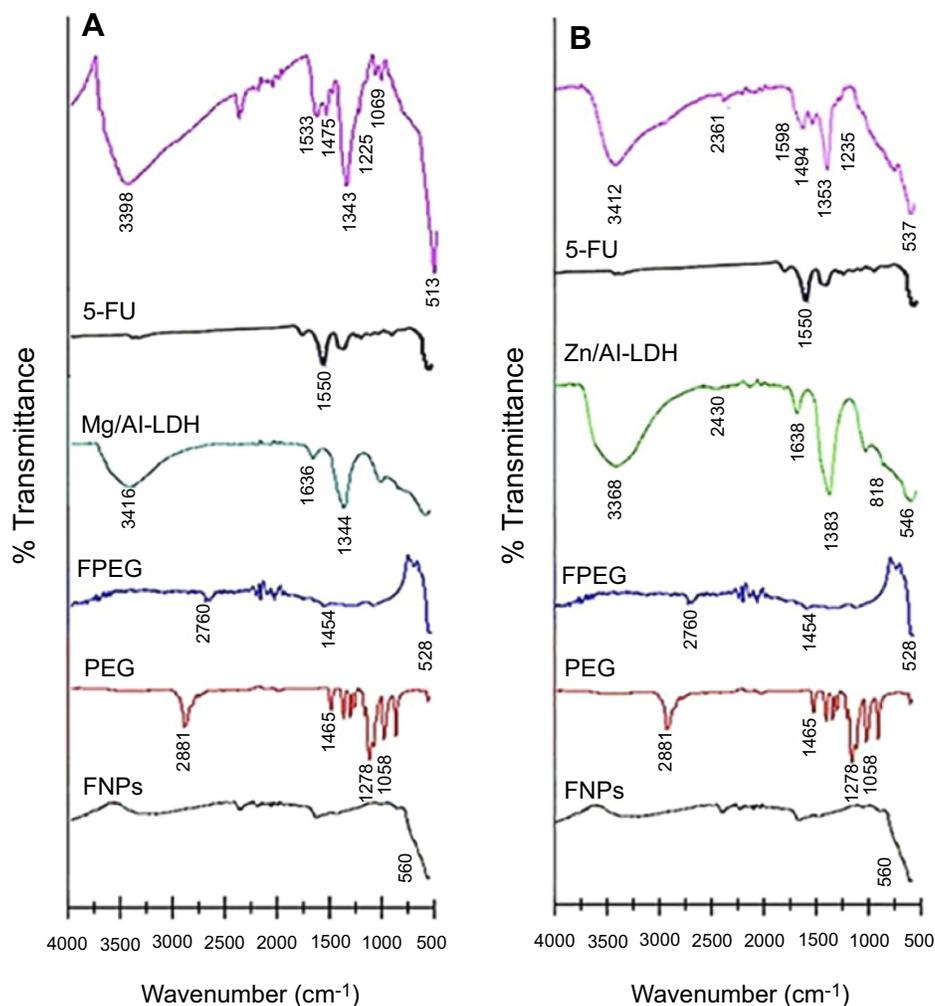

samples	Ms (emu/g)	Mr (emu/g) Magnetization remanent retentivity	Hc (G) coercivity
FNPs	58.987	1.571	24.955
FPEG-Mg/Al-LDH	40.415	1.133	17.727
FPEG-Zn/Al-LDH	27.677	1.222	16.854
core-shell-Mg/Al-LDH	33.472	0.836	14.977
core-shell-Zn/Al-LDH	23.476	0.511	10.292

Although the remanent magnetization and coercivity ( $H_c$ ) of pure  $Fe_3O_4$ , FPEG-MLDH and FPEG-ZLDH nanoparticles were low, all of them retain their superparamagnetic properties due to the high value of saturation magnetization. This means that they do not maintain their magnetic behavior after the removal of the external magnetic field.<sup>68</sup> It should be noted that the synthesis method and the type of nanocarrier, as well as the stabilizer, could affect the value of saturation magnetization.<sup>69,70</sup> Based on the results, the reduction in saturation magnetization of  $Fe_3O_4$  after they were coated could be due to the existence of a layer that covered the iron oxide nanoparticles on the surface and electron exchange between Fe atoms and PEG polymer coated on the surface of  $Fe_3O_4$  nanoparticles that could affect the surface magnetic anisotropy and increase surface spins disorientation. The magnetic properties of the nanoparticles in the formulation can be utilized for target the cancer cells by the application of external magnetic field and in addition, they can also confer on the

hyperthermia treatment applications in addition to the chemotherapeutic effect of 5-FU.<sup>62,71,72</sup>

### Fourier-transform infrared spectroscopy

Fourier-transform infrared spectroscopy (FTIR) spectra for FNPs, MLDH, PEG, ZLDH, 5-FU and FPEG, the nanoparticles co-coated with MLDH and ZLDH are shown in Figure 7. The FNPs shows an absorption band at  $560\text{ cm}^{-1}$  which relates to the stretching of Fe–O in  $Fe_3O_4$ . Band of Fe–O was shifted to  $528\text{ cm}^{-1}$ ,  $513\text{ cm}^{-1}$  and  $537\text{ cm}^{-1}$  for FPEG, sample (a) and (b), respectively. These results confirmed the presence of iron oxide nanoparticles in the synthesized samples which support the XRD result. The characteristic bands of naked PEG appeared at  $2881$  and  $1465\text{ cm}^{-1}$  which can be assigned to C–H stretching and bending vibration, respectively. In addition, two other characteristic bands are observed at  $1278$  and  $1058\text{ cm}^{-1}$  which belongs to the O–H and C–O–H stretching vibration, respectively.<sup>10,73</sup> However, in FPEG nanoparticles,

**Figure 7** FTIR spectra of pure FPNs, PEG, FPEG, Mg/Al-LDH, Zn/Al-LDH and 5-FU, (A) co-coated with Mg/Al-LDH, (B) co-coated with Zn/Al-LDH.

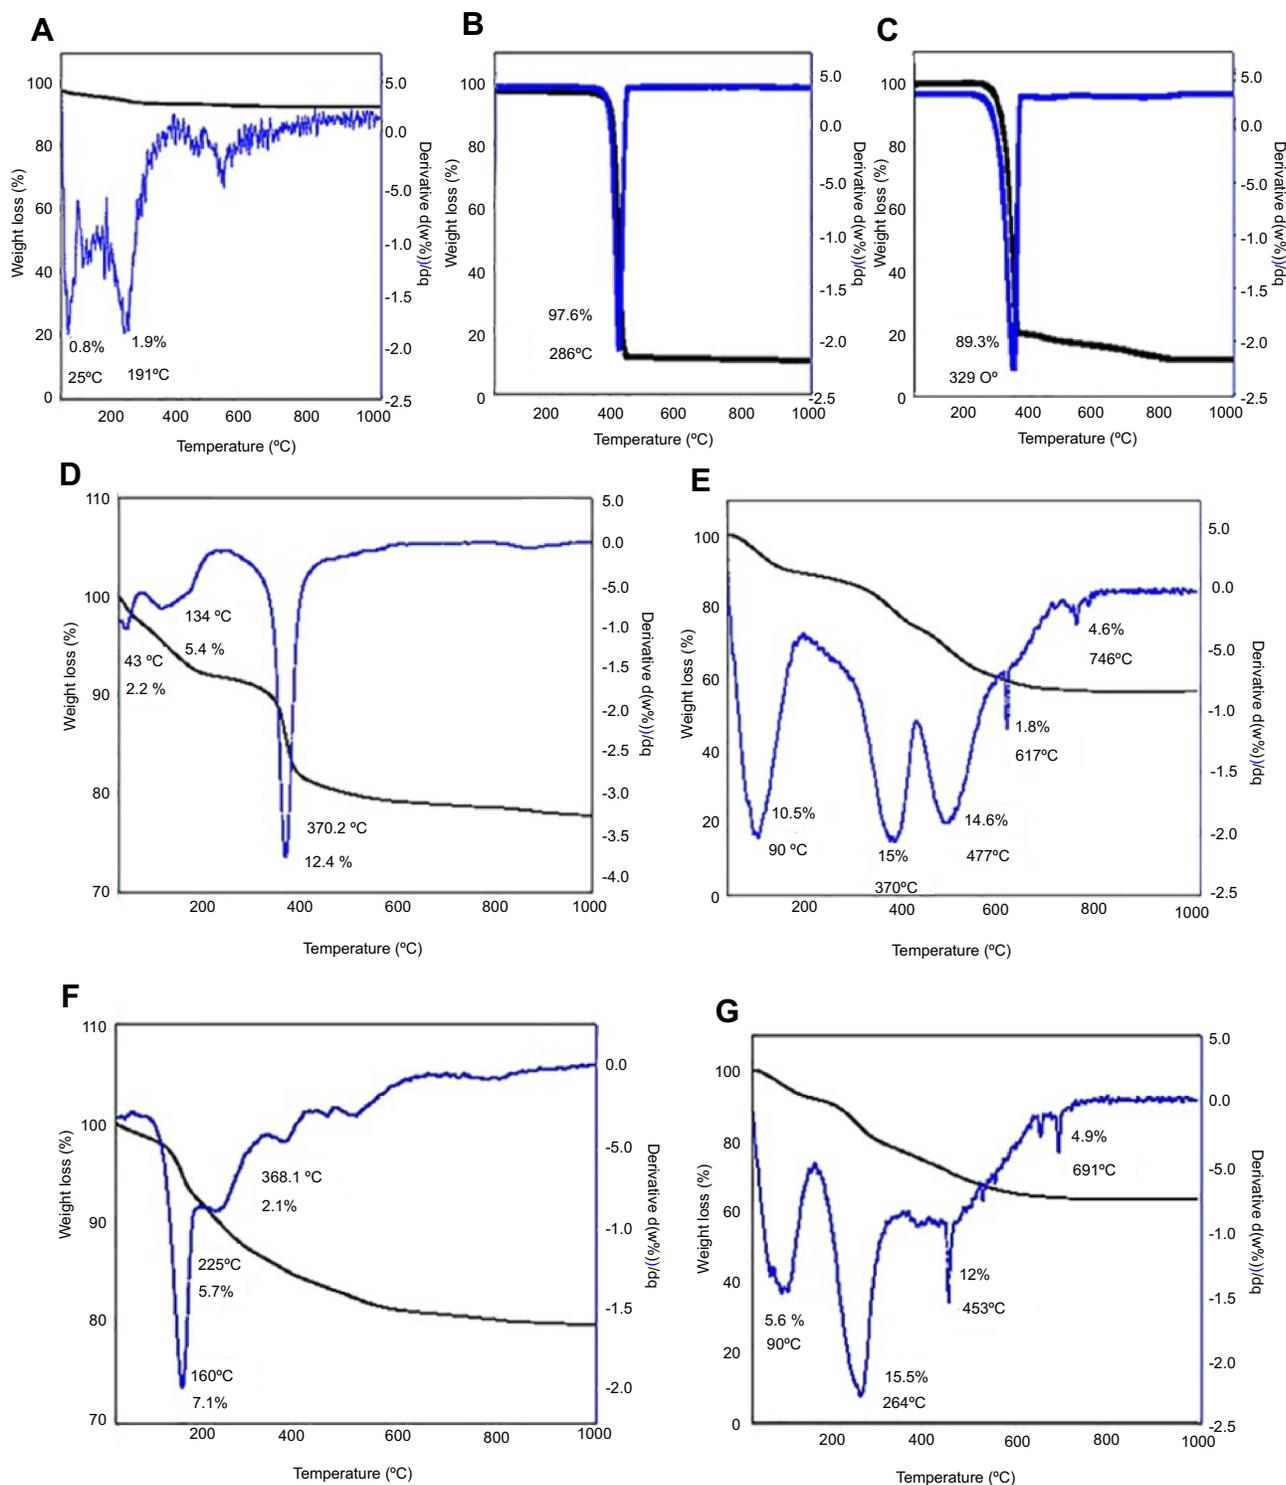

pure PEG spectrum relates to 2881 and 1465  $\text{cm}^{-1}$  were shifted to 2760 and 1454  $\text{cm}^{-1}$  after the coating process. This confirms the coating of PEG on the surface of FPNs. In addition, the FTIR spectra show the characteristic bands of PEG which belong to the C-H, O-H and C-O-H stretching vibrations in the nanoparticles co-coated with Mg/Al-LDH (Figure 7A) shifted to 2360, 1475, 1225 and 1069  $\text{cm}^{-1}$  and in co-coated Zn/Al-LDH (Figure 7B) shifted to 2361, 1494 and 1235  $\text{cm}^{-1}$ , respectively. This indicates that the nanoparticles were successfully coated with PEG together with the LDHs.<sup>58,74</sup>

The FTIR spectrum of 5-FU shows the absorption bands related to primary amines groups at 1550  $\text{cm}^{-1}$  and also an intense, broad band at 1281  $\text{cm}^{-1}$ , belongs to C-N functional group. Absorption bands related to N-H structure was shifted to 1533 and 1589  $\text{cm}^{-1}$  in the nanoparticle of the co-coated with Mg/Al-LDH and

Zn/Al-LDH (samples a and b, respectively). The present of -NH and -CN bands is strong evidence to indicate that 5-FU was loaded on the nanoparticles.<sup>75</sup> The appearance of hydrogen bond related to hydroxyl layers in the nanoparticles of co-coated Mg/Al-LDH confirmed the formation of a bond between LDH and FPEG-drug nanoparticles. For example, the asymmetric and symmetric stretching mode of O-H group in Mg/Al-OH of Mg/Al-LDH at 3416  $\text{cm}^{-1}$  was shifted to 3398  $\text{cm}^{-1}$ .<sup>76</sup> The band at 1636  $\text{cm}^{-1}$  is due to the bending vibration (H-O-H) of interlayer water molecules was shifted to 1622  $\text{cm}^{-1}$ . In addition, the absorption band at 1344  $\text{cm}^{-1}$  belongs to the stretching vibration of C-O, shifted to 1343  $\text{cm}^{-1}$ . The bands at 1000–500  $\text{cm}^{-1}$  are due to vibrational modes of the lattice resulting from the O-Mg-O/Mg-O/Al-O/O-Al-O bonds.<sup>77</sup>

The FTIR spectrum of ZLDH shows a broad band at  $3368\text{ cm}^{-1}$ , attributed to the O–H stretching vibration of LDH layer, and the interlayer water molecules was shifted to  $3412\text{ cm}^{-1}$  in sample b. The bending vibration of H–O–H

is due to the presence of water, gives rise to an absorption band close to  $1638\text{ cm}^{-1}$ . A band at about  $1383\text{ cm}^{-1}$  is attributed to the C–O stretching vibration. However, this bond was moved to  $1353\text{ cm}^{-1}$  in the nanoparticle. In

**Figure 8** TGA/DTG thermograms of (A) FNPs, (B) pure PEG, (C) 5-FU, (D) Mg/Al-LDH, (E) co-coated nanoparticles with Mg/Al-LDH, (F) Zn/Al-LDH, (G) co-coated nanoparticles with Zn/Al-LDH.

addition, the bands at 818 and 546  $\text{cm}^{-1}$  are due to the vibrations of Al-OH and Zn-OH in the layer crystal lattice, respectively. The absorption band due to Zn-OH structure was shifted to 537  $\text{cm}^{-1}$  in sample b. The presence of iron oxide and polymer in the nanoparticles co-coated with MLDH and ZLDH can be confirmed by the presence of the vibration bands at 500 and 2000–3000  $\text{cm}^{-1}$ , which are ascribed to the stretching vibration of Fe-O and C-H, respectively. Furthermore, the absorption band related to the vibration of N-H existed in the drug was found in both samples. Compared to the pure Mg/Al-LDH and Zn/Al-LDH, the O-H stretching band in the nanoparticles co-coated with MLDH and ZLDH was slightly shifted after the intercalation, presumably because of the constraint inside the interlayer space as well as the interaction with the -OH functional group.

## Thermal decomposition

The thermogravimetric and differential thermogravimetric (TGA/DTG) behavior of FNPs, PEG, Mg/Al- and Zn/Al-LDH and 5-FU are shown in Figure 8. The thermal behavior of FNPs (Figure 8A) over the temperature range between 25–1000 °C revealed that two stages of weight loss at 49 °C, with weight loss of 0.8%, and at 263 °C with weight loss of 1.9%; both are attributed to removal of residual water in the sample.<sup>34</sup> For PEG polymer (Figure 8B), one main thermal event was clearly observed,

occurred in the region of 170–433 °C with 97.6% weight loss.<sup>30</sup> The TGA/DTG thermograms for 5-fluorouracil (Figure 8C) indicate a substantial mass loss of about 89.3%, displaying that the 5-fluorouracil undergoes a rapid decomposition.<sup>59</sup>

The weight loss of MLDH was occurred in three stages (Figure 8D). The first one at 43 °C with a total weight loss of 2.2% was observed. The mass reduction occurs below 100 °C can be related to the evolution of the adsorbed water or removal of free and interlayer water.<sup>78</sup> The second sharp mass reduction step at 134 °C (5.4%) is due to the decomposition of dihydroxylation of the layers and the intercalated anions. The thermogravimetric curve shows one mass reduction at 370 °C (12.4%) and this is due to the decomposition of the interlayer of  $\text{NO}_3$  and dehydroxylation of the layers followed by the collapsed of the layered structure. The last mass reduction is due to the formation of  $\text{MgAl}_2\text{O}_4$  spinal phase.<sup>19</sup> Figure 8E displays the weight loss of the nanoparticles co-coated with Mg/Al-LDH at 23–992 °C with five weight losses; 23–182 °C (10.5%), 182–415 °C (15%); 415–597 °C (14.6%); 615–717 °C (1.8%) and 717–808 °C (4.6%).

Zn/Al-LDH thermogram in Figure 8F shows a mass loss at 160 °C which corresponds to 7.0 %, owing to the removal of water molecules that has hydrogen bonding with the interlayer anion,<sup>79,80</sup> The second decompositions

**Table 2** Elemental composition of the nanoparticles

Sample	C%*	H%*	N%*	Zn%**	Mg%**	Al%**	Fe%**
FNPs	0.02	0.54	1.02	–	–	–	47
PEG	52.69	8.98	1.64	–	–	–	–
Mg/Al-LDH	–	3.18	4.64	–	7.3	4.5	–
Zn/Al-LDH	–	2.37	4.45	6.8	–	5.2	–
5-FU	37.76	2.36	21.5	–	–	–	–
co-coated with MLDH	2.32	2.90	0.16	–	2.1	3.4	13.1
co-coated with ZLDH	5.49	2.26	0.24	3.8	–	3.3	21.3

Notes: \*Calculated from CHNS analysis; \*\*Calculated from ICP-ES analysis.

**Table 3** Percentage of elements in the nanoparticles

Sample	C%	H%	N%	Zn%	Mg%	Al%	Fe%
FNPs	–	0.54	0.07	–	–	–	8.5
PEG	4.4	8.98	0.2	–	–	–	–
Mg/Al-LDH	–	3.18	0.4	–	0.3	1.7	–
Zn/Al-LDH	–	2.37	0.4	0.1	–	0.2	–
5-FU	3.2	2.36	1.5	–	–	–	–
NPs co-coated with Mg/Al-LDH	0.2	2.90	0.02	–	0.1	0.1	2.3
NPs co-coated with Zn/Al-LDH	0.4	2.26	0.01	0.06	–	0.1	3.8

might be due to dehydroxylation of basic LDH layers at 228 °C with 5.7% weight loss. The third event at 368 °C results of the loss of interlayer carbonate species.<sup>81</sup> Similarly, TGA curves of the co-coated sample with Zn/Al-LDH shows four decompositions (Figure 8G). The one at 90 °C was about 5.6%, the second and third stages were at 162–366 °C and 366–641 °C, with 15.5% and 12.0% weight loss, respectively. Finally, the final residue was decomposed with a weight loss of 4.6%.

Comparing the TGA thermograms of all the FNPs, PEG, 5-FU, MLDH, ZLDH with the synthesized nanoparticles, it is clear that the resulting synthesized nanoparticles are composed of polymer (PEG), drug (5-FU) and the nanocarriers (LDHs).

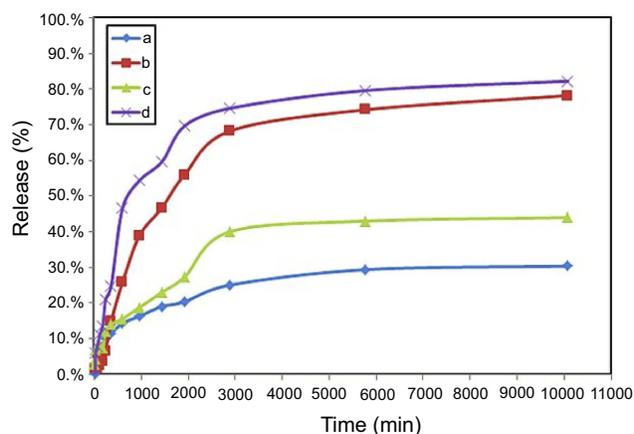

## Elemental composition by CHNS and ICP-ES analyses

The elemental composition analysed by ICP-ES for the pure MLDH and ZLDH (Table 2) was found to be Mg (7.3%), Al (4.5%) and Zn (45.0%), Al (5.2%). The results confirmed the formation of both nanocarriers, LDHs as indicated by the XRD diffractograms and the EDX results of the samples. The ICP-ES results of the nanoparticles in Table 3 also indicate the presence of Mg, Zn and Al, although their percentages are low, owing to the presence of other chemicals from the other molecules. The presence of Fe, which was used as the core, C and O also were observed in the ICP-ES and CHNS data, indicating the successful coating of iron oxide outer layer with the polymer. Additionally, the presence of N which specifically available in the drug structure of the 5-FU was also

detected from the CHNS analyses, which confirm the presence of the drug in the LDH hosts.

## Drug release behavior

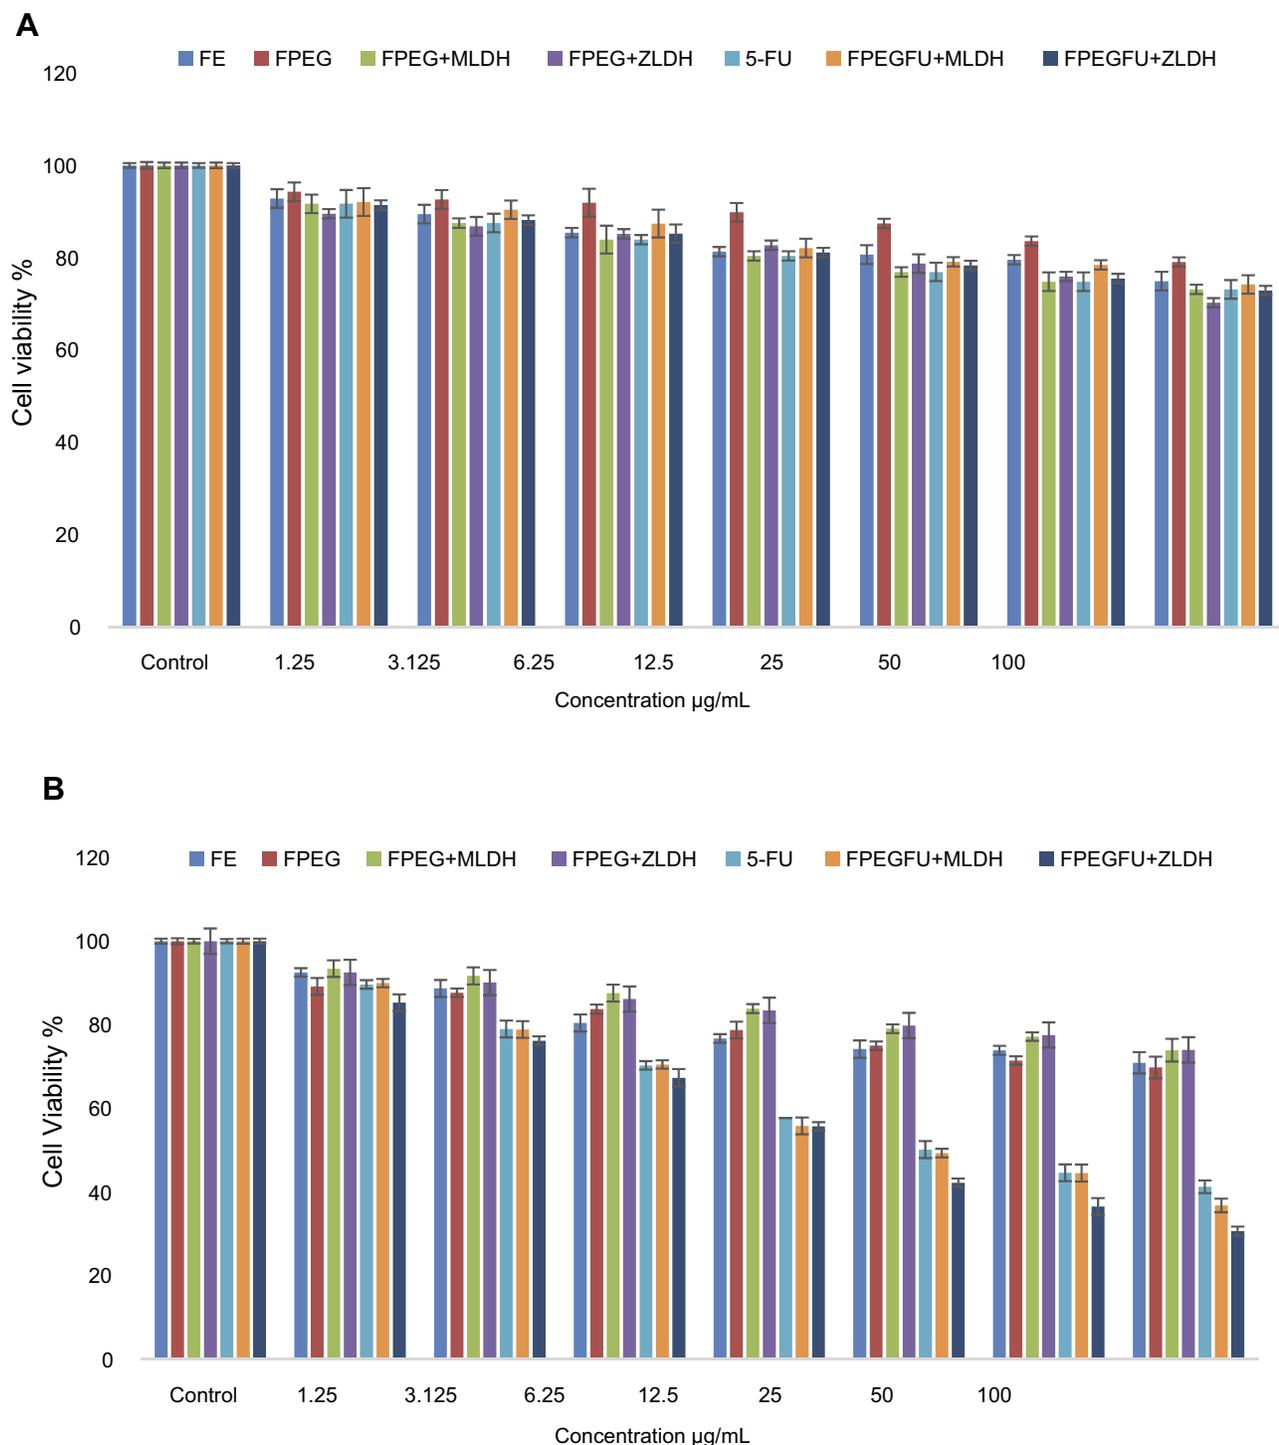

The releases behavior of 5-fluorouracil in PBS solution is plotted in Figure 9. It can be found that both of the 5FU releases at a pH value of 4.8 and 7.4 displayed the trend is almost the same. After 48 hrs, the drug release plateaus were all achieved, indicating that the drug-co-coated nanoparticles with Mg/Al-LDH and Zn/Al-LDH demonstrated obviously slow and sustained release behavior. Meantime, 81% and 78% of the loaded 5FU from co-coated nanoparticles with Mg/Al-LDH (FPEG-FU-MLDH) and co-coated nanoparticles with Zn/Al-LDH (FPEG-FU-ZLDH) were released in the PBS solution at pH 4.8, respectively. Meantime, 43% and 30% of the loaded 5FU from FPEG-FU-MLDH and FPEG-FU-ZLDH nanoparticles were released in the PBS solution at pH 7.4, respectively. The release profile in Figure 9 indicates the maximum percentages of drug release in pH 4.8 were higher than pH 7.4. Meaning that the 5FU-loaded FPEG-FU-MLDH and FPEG-FU-ZLDH nanoparticles had a pH-dependent characteristic for controlling release. The fast release of 5FU was mainly attributed to the higher of the 5FU-loaded in co-coated nanoparticles in an acidic environment than that in high pH value. Certainly, the interaction decreasing between 5-fluorouracil molecular and the carriers due to the breaking of the bonds between the polymer and the drug in the acidic PBS solution may play a role. It is worth noting that, The drug to be almost quickly released at the beginning in FPEG-FU-MLDH and FPEG-FU-ZLDH nanoparticles, in the phosphate-buffer solution with pH 4.8 underwent release within 32 and 48 hrs, respectively. While in pH 7.4 the release was about in the first 10 and 16 hrs. It revealed that the drug release process has a slow, stable and excellent controlled-release property in pH 7.4 through the ion exchange process.

**Figure 9** Cumulative release profile of 5-fluorouracil from co-coated nanoparticles with Zn/Al-LDH in phosphate-buffer solution at (A) pH 7.4, (B) pH 4.8 and co-coated nanoparticles with Mg/Al-LDH in phosphate-buffer solution at (C) pH 7.4, (D) pH 4.8.

## In vitro cell cytotoxicity assay

All the cytotoxicity assays were carried out in triplicates and the standard deviations were calculated and are incorporated in the respective bar graphs. For the calculation of IC<sub>50</sub>, we plot the x- against the y-axis and converted the x-axis values (conc.) to their log values, followed by nonlinear regression (curve fit) under the xy analysis to obtained a straight line equation fit,  $y = ax + b$ , from which the regression line and then inhibition IC<sub>50</sub> was calculated.

**Figure 10 (A)** Cytotoxicity assay of iron oxide (Fe), FPEG, FPEG-MLDH, FPEG-ZLDH, 5-Fluorouracil, core-shell nanoparticles, FPVA-FU-MLDH and FPVA-FU-ZLDH against normal 3T3 cells at 72 hrs. **(B)** Cytotoxicity assay of iron oxide (Fe), FPEG, FPEG-MLDH, FPEG-ZLDH, 5-fluorouracil, core-shell nanoparticles, FPVA-FU-MLDH and FPVA-FU-ZLDH against HepG2 cells at 72 hrs of incubation.

## Cytotoxicity studies on normal fibroblast, 3T3 cells

Cytotoxicity studies were conducted by treating iron oxide (Fe), FPEG, FPEG-MLDH, FPEG-ZLDH, 5-fluorouracil, core-shell nanoparticles; FPVA-FU-MLDH and

FPVA-FU-ZLDH, with normal fibroblast, 3T3 cells. Various gradient concentrations of the samples were incubated for a maximum of 72 hrs with the 3T3 cells. Cell viability was determined using the standard MTT assay protocol. [Figure 10A](#) shows the percentage cell

viability of the 3T3 cells after 72 hrs incubation for all the samples. All of the samples including iron oxide (Fe), FPEG, FPEG-MLDH, FPEG-ZLDH, 5-fluorouracil, core-shell nanoparticles; FPVA-FU-MLDH and FPVA-FU-ZLDH were found to be biocompatible and nontoxic, as the cell viability was found to be more than 70% after 72 hrs incubation. This suggests that the designed anticancer nanoparticle formulation is biocompatible with normal cells and would be very useful for targeting the cancer cells without damaging/harming the normal tissues. The statistics ANOVA revealed that no significant difference was found among the samples groups at individual concentrations using the ANOVA and Duncan's Multiple Range test.

## Anticancer action against liver cancer cells, HepG2

To study the anticancer activity of iron oxide (Fe), FPEG, FPEG-MLDH, FPEG-ZLDH, 5-fluorouracil, core-shell nanoparticles, FPVA-FU-MLDH and FPVA-FU-ZLDH, the samples were treated with liver cancer cells, HepG2 (Figure 10B). Different concentrations of the above samples were incubated with liver cancer cells, HepG2 for 72 hrs and cell viability was determined by the MTT assay protocol. The empty carriers; Fe, FPEG, FPEG-MLDH, and FPEG-ZLDH did not show any inhibitory action against liver cancer cells, HepG2. The  $IC_{50}$  of the pure drug, 5-FU against liver cancer cells, HepG2 was found to be 32.73  $\mu\text{g/mL}$ . The  $IC_{50}$  of the core-shell nanoparticles; FPEG-FU-MLDH and FPVA-FU-ZLDH were found to be 28.88  $\mu\text{g/mL}$  and 20.09  $\mu\text{g/mL}$ , respectively. The effective  $IC_{50}$  which is the actual amount of 5-FU present in  $IC_{50}$  of the anticancer nanoparticle was calculated from the percentage of the drug, 5-FU loading which is 68 and 51% for FPEG-FU-MLDH and FPVA-FU-ZLDH, respectively, which were determined using the HPLC analysis. These results suggest that the core-shell nanoparticles of FPEG-FU-MLDH at 28.88  $\mu\text{g/mL}$  and FPVA-FU-ZLDH at 20.09  $\mu\text{g/mL}$  have much better anticancer activity compared to the free drug, 5-fluorouracil. Overall, the study shows that FPVA-FU-ZLDH has better cytotoxicity compared to FPEG-FU-MLDH, even though the drug loading percentage of FPVA-FU-ZLDH is lower, which is only 51%.

Statistical analysis was determined using several softwares; SPSS and ANOVA and Duncan's Multiple

**Table 4** The half maximal inhibitory concentration ( $IC_{50}$ ) value for iron oxide (Fe), FPEG, FPEG-MLDH, FPEG-ZLDH, 5-fluorouracil, core-shell nanoparticles; FPVA-FU-MLDH and FPVA-FU-ZLDH samples tested on 3T3 and HepG2 cell lines

Nanocomposites	$IC_{50}$ ( $\mu\text{g/mL}$ )	
	3T3 cell lines	HepG2 cell line
Fe	N.C	N.C
FPEG	N.C	N.C
FPEG-MLDH	N.C	N.C
FPEG-ZLDH	N.C	N.C
5-fluorouracil	N.C	32.73 $\mu\text{g/mL}$
FPVA-FU-MLDH	N.C	28.88 $\mu\text{g/mL}$
FPVA-FU-ZLDH	N.C	20.09 $\mu\text{g/mL}$

**Abbreviation:** N.C, No cytotoxicity.

Range test. The significant differences were found between the empty carriers, iron oxide (Fe), FPEG, FPEG-MLDH, FPEG-ZLDH, free drug 5-fluorouracil, core-shell nanoparticles; FPEG-FU-MLDH and FPVA-FU-ZLDH. The core-shell nanoparticles; FPEG-FU-MLDH and FPVA-FU-ZLDH were found significantly different from all the other samples at concentrations of 6.25 to 50  $\mu\text{g/mL}$  with ( $P$ -values of  $<0.5$ ). At a concentration of 3.125–100  $\mu\text{g/mL}$ , the samples 5-FU, FPVA-FU-MLDH and FPVA-FU-ZLDH were significantly different from the empty carrier. The value was found to be  $<0.05$ .

The samples; iron oxide (Fe), FPEG, FPEG-MLDH, FPEG-ZLDH, 5-fluorouracil, core-shell nanoparticles; FPVA-FU-MLDH and FPVA-FU-ZLDH showed the anticancer effect towards the cell line is in a dose-dependent manner. The half maximal inhibitory concentration value ( $IC_{50}$ ) of all the samples is given in Table 4. The  $IC_{50}$  values of the nanoparticles determined based on percentage drug loading clearly indicates that the synthesised nanoparticles have a better anticancer effect than the drug in their free forms.

## Conclusion

Magnetite nanoparticles coated with polyethylene glycol/layered double hydroxide/5-fluorouracil were successfully prepared via co-precipitation method. When Mg/Al-LDH was used as the co-coating agent, the nanocarrier enhanced the percentage of drug loading with narrow size distribution and smaller particle size distribution. The average size distribution of the Mg/Al-LDH co-coated agent was found to be about 69 nm, compared to 82 nm for the one co-coated with Zn/Al-LDH. In addition, the particle size of

the nanoparticles depends on the type of the nanocarrier; the one co-coated with Mg/Al-LDH is smaller than the one co-coated with Zn/Al-LDH. It was also shown that the nanoparticles can retain their superparamagnetic properties; even they were co-coated with 5-FU/LDH. Based on their physico-chemical properties, the synthesized nanoparticles can be further explored to be used as multifunctional nanotheranostics for targeted delivery using an external magnetic field, as hypothermia agent for cancer cells in addition to their chemotherapeutic property.

## International Journal of Nanomedicine

Dovepress

### Publish your work in this journal

The International Journal of Nanomedicine is an international, peer-reviewed journal focusing on the application of nanotechnology in diagnostics, therapeutics, and drug delivery systems throughout the biomedical field. This journal is indexed on PubMed Central, MedLine, CAS, SciSearch®, Current Contents®/Clinical Medicine,

Journal Citation Reports/Science Edition, EMBase, Scopus and the Elsevier Bibliographic databases. The manuscript management system is completely online and includes a very quick and fair peer-review system, which is all easy to use. Visit <http://www.dovepress.com/testimonials.php> to read real quotes from published authors.

Submit your manuscript here: <https://www.dovepress.com/international-journal-of-nanomedicine-journal>
