patients with **Background:** Previous studies have suggested monary disease (COPD) have a higher incide of de ession and an increased risk of e aimed elucidate the association developing various depression-related com cation between the serum human epididymal tein 4 (HEand depressive symptoms in patients with COPD.

Methods: The data on 219 participants with PD from The Irish Longitudinal Study on Ageing (TILDA) were analysed for the association between serum HE4 levels and depressive symptoms, accounting or relevant confounding factors. All the COPD participants were prospectively followed up or a median eriod of 48 months. Cox proportional hazards analysis was used to evaluate be predictive value of serum HE4 for predicting depression events in these

Results: Multivar ession analysis revealed that serum HE4 was independently ression score after adjusting for age, sex, BMI, current smoking drinkin status, admission systolic and diastolic BP, CVD history and laborameasurements in Latients with COPD at baseline (S β = 0.149; 95% CI, 0.069–0.201; Multivariate Cox proportional hazards analysis revealed that serum HE4 6, 95% CI 1.691–5.109, P<0.001) was an independent prognostic factor for ents in these COPD patients.

enclusion: Our results showed that serum HE4 is significantly and independently assowith depression events. Serum HE4 may enable the early recognition of depressive symptoms among COPD patients.

Keywords: human epididymis protein 4, chronic obstructive pulmonary disease depressive symptoms, prognostic value

Introduction

Previous studies have suggested a close association between chronic obstructive pulmonary disease (COPD) and depression. 1,2 Patients with COPD have a high risk of depression, which is associated with poor treatment adherence and poor prognosis, as well as a high prevalence of depression-related complications, including cardiovascular diseases (CVDs) and all-cause mortality.³⁻⁵ The incidence of depression is higher in individuals with COPD than in those without COPD.⁶ Although the precise mechanisms are currently poorly understood, increasing the levels of inflammation and oxidative stress in COPD may play an important role in increasing the risk of depressive symptoms.^{7–9} Therefore, identifying valuable predictors

Shu and Wang Dovepress

or controllable risk factors is very significant to prevent and treat depression in patients with COPD. The early prediction of depression events in COPD patients may provide an opportunity to develop strategies to reduce the medical burden and even improve prognosis.

Human epididymis protein 4 (HE4), a secretory protein highly expressed in the human epididymis, is encoded by the WFDC2 gene located on chromosome 20g12-13.1.¹⁰ The mature HE4 protein is a 20- to 25-kDa glycoprotein found on membranes, in the cytoplasm of cells and in circulation. Studies have reported initially that HE4 is highly expressed in malignant tumors, such as ovarian cancer and endometrial cancer tumors. 11-13 However, other studies have also shown that HE4 is moderately expressed in multiple normal and abnormal tissues in the human body, such as the respiratory tract and other tissues. 14,15 Higher HE4 expression in the respiratory tract plays a very important role in the process related to immune defense and the inflammatory response. 14,15 Other WFDC proteins have also been correlated with inflammatory processes. 16-18 Previous studies have shown the strong links between depression and the chronic and systemic inflammatory levels. As a chronic inflammatory disease. COPD can hasten the occurrence of depressi and contribute to a higher rate of depression. 19-21 Given 16 - 18the close association between HE4 and inflampa we hypothesized that HE4 might be as ciated with depressive symptoms in COPD patients.

Until now, few studies have expliced the association between the serum HE4 levels and to depression core in patients with COPD. This study ain of to investigate whether increased HE4 levels contribute to the increased risk of depression events, independent of confounding factors. This study was the first to explore the prognostic value of HE4 for padicting depression events in COPD patients.

Materials and Methods

Study Population

Study participants from The Irish Longitudinal Study on Ageing (TILDA) were evaluated in this study. TILDA, comprising middle-aged and elderly adults (age ≥49 years), is a large prospective cohort study with repeated assessments at 2-year intervals in the Republic of Ireland. A nationally representative sample was obtained from all residential addresses in the Republic of Ireland using the RANSAM sampling procedure, with a response rate of

62% (N=8594) for wave 1 (2009–2011).²² Details on the method and design of the cohort study were published elsewhere.²² In summary, the TILDA study comprised (1) a self-completed questionnaire; (2) a computer-aided personal interview (CAPI) performed by trained interviewers in the included subjects' homes; and (3) a health examination performed by well-trained research nurses. All the subjects who completed the CAPI and self-completed questionnaire were invited to attend one of two health centers for a health examination. As one part of the comprehensive health examination, all the subjects completed a health assessment, which cluded a urate measurements of biochemical tests. Fur study in uded the subjects who completed the CAPI, If-completed questionnaire and health examination during w 1 who had accurate serum HE4 ta translyze the associations between serum 124 and e depression score and who had a complete pression steer wave 3 (a follow-up period of 4 years). etails on the measuring method of HE4 argum indical were published elsewhere. 22 In our dudy, participants who had a self-reported doctor's diagosis of a OPD history (N=219) in wave 1 were included for the halysis. The guidelines the diagnosis of COPD was afirmed by post-bronchodilator spirometry ing to the Global Initiative for Chronic ostructive Lung Disease (GOLD). Included subjects with a cancer history (N=11) were excluded from the dudy. In general, the anonymized TILDA data are available to scientific research personnel who meet the criteria for access from the Interuniversity Consortium for Political and Social Research at the University of Michigan and the Irish Science Data Archive at University College Dublin. TILDA also approves applications for privileged access to the data set via a website called the "hot desk" (www.tilda.ie). According to the Declaration of Helsinki guidelines, the TILDA study was approved by the Trinity College Research Ethics committee, and all participants provided informed written consent.

Depression Score

In wave 1, the Center for Epidemiological Studies Depression (CES-D) scale was used to calculate the depression score.²³ A cut-off score of 16 was considered indicative of depressive symptoms.²⁴ In wave 3, a short form of the CES-D scale was used, and a cut-off score of 10 indicated a depression event.²⁴ The CES-D scale has been used widely in epidemiological studies and is

Dovepress Shu and Wang

appropriate for use in our study with middle-aged and elderly subjects.

Statistical Analyses

The Kolmogorov-Smirnov test was used to assess the normality of the data. The data that were not normally distributed were expressed as medians (interquartile range [IQR]). Normally distributed data were presented as means \pm SD. Categorical variables were presented as n (%). Multivariate linear regression analysis was performed to identify the independent association between the serum HE4 levels and depression score in COPD patients in the wave at baseline. The Cox model with time-dependent covariates was used to identify the independent prognostic value of the HE4 levels for depression events in patients with COPD. We adjusted for confounding factor data relevant to COPD and depression even if the factors were not significantly associated with depression in the univariate analysis because they are key clinical variables and may be associated with depression in the multivariate but not univariate analyses. Additionally, sensitivity analysis by adding "taking antidepressant medications" as a covariate was further performed to assess the association between the serum HE4 and depression events. Stratified analysis by adding "CVD history (a covariate was also performed to assess whether the ass tion of serum HE4 with depression events w CVD history. All the analyses were perfected u 25.0. $P \le 0.05$ was considered to be startically

Results

Characteristics of the Study Subjects at Baseline (N=21)

To assess the serum evels of 2.24 in patients with COPD, 438 age- and sex-matche using ects (moch 1:2) without COPD were selected as the control grow. The serum HE4 levels in patients with COD were sunficantly higher than those of the control subjects (control subjects (control subjects) (control subjects). The characteristics of the patients with COPD are presented in Table 1. The mean age of anothe COPD patients was 69.5 (57.4–78.6) years, and the number of men was 125 (57.1%). The mean depression score was 7.4±4.2 in the patients with COPD.

Serum HE4 Was Independently Associated with the Depression Score in 219 Patients with COPD

To assess the association between the serum HE4 levels in COPD patients and the depression score, multivariate linear

regression analysis was performed (Table 2). The crude model indicated that higher serum HE4 levels were significantly associated with the depression score without adjustment. After adjusting for age, sex, BMI, current smoking status, current drinking status, admission systolic and diastolic BP and CVD history, the results of Model 1 were found to be similar to those of the crude model. This association remained statistically significant and changed minimally after adding laboratory measurements to Model 2.

Cox Proportional Hazards Analyses of the Prediction of Depression Events in Patients with COPD

All the included COPD patients (N=219) were prospectively followed up for a median period of 48 months. Depression events occurred in 38 of the included COPD patients. To determine whether the serum HE4 levels

were independently associated with depression events, multivariate Cox proportional hazards regression analysis was performed (Table 3), revealing that HE4 (HR=2.216, 95% CI: 1.691–5.109, P<0.001) was an independent prognostic factor for depression events after adjusting for age, sex, BMI, current smoking status, current drinking status, admission systolic and diastolic BP, CVD history and laboratory measurements. Kaplan-Meier analysis demonstrated that COPD patients with serum HE4 levels above the mean (122.4 [pmol/L]) had a significantly higher rate of depression events than tho with serum HE4 levels below the mean value (Log rank test, P<0.001, data not shown).

We performed an additional sensitive analy evaluate the association of the serum HE4 events (end points) in COPD subjection s by add "taking antidepressant medications" as variate (Ta Sensitivity analysis showed that higher E4 levels were still independently associated with a higher ask of depression events (HR=2.02 95% 6. 1.482–4.584, P<0.001). Additionally, stratified an s show that the significant HP levels and depression association bet een e seru.

events in COPD patients was not affected by CVD history (Table 5).

Discussion

In this study, multivariate Cox proportional hazards analysis suggested that serum HE4 was an independent prognostic factor for depression events in patients with COPD. We first showed that serum HE4 was closely associated with the depression score at baseline and depression events after a follow-up of 4 years, a finding that may be partly or mostly explained by the mechanistic research .48Uh. studies. 19-21 These studies demong ated that chi ic inflammation caused by COPD promote depression increased HE4 levels may e the result f the aggravation of inflammation in COO paties, and it explain why higher serum HE4 vels ssociate with an increased risk of depression events in PD reaches, a finding that is consistent van ou hypothesis and results. Additionally, some studies have suggested that increased HE4 levels are related to renal dys unction. ^{29,30} Our COPD subjects no history **f** kidney disease and their eGFR values ormal; thus the influence of renal function abnormals was excluded. Studies have also reported ities on WE4 is associated with cancer (eg, ovarian, cervical, lag, and breast) and some other serious diseases. 11-13 To eliminate the impact of the diseases on this study, COPD tients with a cancer history were excluded from the baseline assessment. It is clinically significant to determine the independent risk factors or predictors of depressive symptoms in COPD patients. The early detection of depression events in these COPD patients may help develop strategies to reduce the medical burden and improve the prognosis. Our results implied that serum HE4 might be a highly sensitive biomarker for the early recognition of depression events in COPD patients.

Our study has several strengths, including the popula based sample size. The results of the study many to the literature in three different ways. rst, the ata we from TILDA, a longitudinal study of a na middle-aged and elderly population. The a analysis of studies with a follow-up of 4 ars proves serum HE4 levels are closely related to the occurrence of depression outcomes expanding the are longitudinal research on the acciation etween HE4 and depression presently. Second, st found a positive correlation between the riplevels and pression in a middle-aged and eld by population with OPD after adjusting for multiple releve to mountaing factors. Finally, to better explain a wide range of potential confounding factors, our results using continuous nood scores avoided arbitrary cut-offs of continuous mood traits. This association was significant after adjustment for possible confounders.

Finally, our study had some limitations. First, many participants in the TILDA study were not included in our study because some data were lost, leading to some deviations in our results. Time-varying confounding factors, such as the BMI, in our study, may interfere with our results on the associations between the serum HE4 levels

and pression events. Second, we used self-reported measures to define major depression, possibly resulting in misclassification. Third, more studies must be performed to identify the value of the serum HE4 levels for predicting depression. Given the close relationships between serum HE4 and many malignant tumors or renal function, our results are not applicable to the general population.

Conclusions

Serum HE4 is an independent prognostic factor for predicting depression events in patients with COPD. Serum HE4 might allow the early recognition of COPD patients at risk of developing depression.

International Journal of Chronic Obstructive Pulmonary Disease

Dovepress

Publish your work in this journal

The International Journal of COPD is an international, peer-reviewed journal of therapeutics and pharmacology focusing on concise rapid reporting of clinical studies and reviews in COPD. Special focus is given to the pathophysiological processes underlying the disease, intervention programs, patient focused education, and self management protocols. This journal is indexed on PubMed Central, MedLine and CAS. The manuscript management system is completely online and includes a very quick and fair peer-review system, which is all easy to use. Visit http://www.dovepress.com/testimonials.php to read real quotes from published authors
