Purpose: Undiagnosed Chronic Obstructive Pulmonary Disease (COPD) results in high morbidity, disability and mortality in India. Effective strategies for active COPD screening in community settings are needed to increase early identification, risk reduction and timely management. The objective of this study was to test the diagnostic accuracy of a sequential two-step screening strategy to detect COPD, implemented by community health workers (CHWs), among adults aged ≥ 40 years in a rural area of North India.

Patients and Methods: Trained CHWs screened all consenting ($n=3256$) eligible adults in two villages using the Lung Function Questionnaire (LFQ) to assess their COPD risk and conducted pocket spirometry on 268 randomly selected (132 with high risk ie LFQ score ≤ 18 and 136 with low risk ie LFQ score > 18) individuals. Subsequently, trained researchers conducted post-bronchodilator spirometry on these randomly selected individuals using a diagnostic quality spirometer and confirmed the COPD diagnosis according to the Global Initiative for Obstructive Lung Disease (GOLD) criteria (FEV_1/FVC ratio < 0.7).

Results: This strategy of using LFQ followed by pocket spirometry was sensitive (78.6%) and specific (78.8%), with a positive predictive value of 66% and negative predictive value of 88%. It could accurately detect 67% of GOLD Stage 1, 78% of GOLD Stage 2, 82% of GOLD Stage 3 and 100% of GOLD Stage 4 individuals with airflow limitation.

Conclusion: COPD can be accurately detected by trained CHWs using a simple sequential screening strategy. This can potentially contribute to accurate assessment of COPD and thus its effective management in low-resource settings.

Keywords: COPD, sensitivity and specificity, screening, community health workers, spirometry

Introduction

Chronic Obstructive Pulmonary Disease (COPD) is one of the most common causes of morbidity, disability, and mortality in India.¹ It remains largely undetected due to a lack of awareness among the community and under-diagnosis in clinical practice.^{2,3} Spirometry is the most reproducible, objective and a non-invasive lung function test.⁴ Spirometry measures the ratio of forced expiratory volume in one second (FEV_1) to the forced vital capacity (FVC) and the presence of post-bronchodilator $FEV_1/FVC < 0.7$ confirms the presence of airflow limitation which is required for the diagnosis of COPD.⁴ There is a shortage of skilled medical

personnel to conduct spirometry in primary care settings in India, resulting in under-diagnosis, thus impeding timely management of COPD.⁵

Screening early for COPD can facilitate the early institution of pharmacological treatment, higher smoking cessation rates, greater uptake of vaccination against influenza and pneumococcal pneumonia, participation in pulmonary rehabilitation, and improved identification and better management of comorbidities.^{6,7} Screening questionnaires and simple devices like pocket spirometers have been successfully used for screening and detecting hidden COPD cases in primary care settings of high-income countries.^{8–11} Pocket spirometers measure FEV₁/FEV₆ ratio to assess the airflow limitation instead of FEV₁/FVC ratio which is measured by a diagnostic quality spirometer.¹² The FEV₆ has been identified as a valid estimate of FVC and is easier to perform consistently outside of a controlled laboratory environment and therefore can be used for screening of COPD among those with high-risk.¹² In low and middle-income countries (LMICs) like India, the COPD burden is rising and constrained health infrastructure, including limited skilled human resources, impede the implementation of effective COPD screening and detection programs, especially within rural primary health care settings. Training and involving community health workers (CHWs), who comprise the largest health workforce in rural settings in India, in screening may provide an effective means of early detection.^{13,14} Thus, this study aimed to test the diagnostic accuracy of a sequential, two-step screening strategy implemented by CHWs, using the Lung Function Questionnaire (LFQ) and pocket spirometry (PS) to detect individuals with COPD in rural India.

Patients and Methods

A prospective diagnostic accuracy study was nested within one site (Sonipat, Haryana, India) of a large community-based research project entitled “UDAY”. “UDAY” is a comprehensive diabetes and hypertension prevention and management program in India; the detailed methodology has been published previously.¹⁵ Briefly, UDAY was implemented in a population of about 100,000 each in rural and urban subsites in north India (Sonipat district in Haryana state) and south India (Visakhapatnam district in Andhra Pradesh state). In each rural and urban subsite, trained project staff referred to as CHWs (1 CHW per 5000 population) selected from the same area, conducted surveys and screened adults aged ≥ 30 years for the presence of diabetes and hypertension, subsequently linking

those at high risk or with diabetes and/or hypertension to the healthcare system. CHWs also provided tailored health education to patients regarding non-pharmacological management of diabetes and hypertension and educated the general population about modification/reduction of risk factors.

Study Population

In this study, we included individuals aged ≥ 40 years from the two largest villages selected by purposive sampling from the UDAY rural area in north India. Individuals with a cognitive impairment limiting their ability to answer the study questions and those who were bedridden or terminally ill were excluded.

Definitions and Study Tools

COPD was defined using the Global Initiative for Obstructive Lung Disease (GOLD) criteria, ie, the forced expiratory volume in 1 second (FEV₁) and its ratio to Forced Vital Capacity (FVC), with the FEV₁/FVC < 0.7 post-administration of a bronchodilator.⁴ Severity of airflow limitation was defined using GOLD criteria, ie, post-bronchodilator FEV₁ $\geq 80\%$ predicted as mild, $50\% \leq$ to $< 80\%$ predicted as moderate, $30\% \leq$ to $< 50\%$ predicted as severe and $< 30\%$ predicted as very severe.⁴ For screening, we used the Lung Function Questionnaire (LFQ), which is a case-finding tool to detect individuals for further confirmatory evaluation using spirometry.¹⁶ Two independent interpreters translated the LFQ into the local Hindi language. The two versions were combined by the first author and the translated version was back-translated by two independent research professionals. The Hindi language version was tested for face-validity by administering the questionnaire to 10 COPD patients in the community and was finalized in consultation with a local chest physician and a general physician. CHWs used the COPD-6 (Vitalograph model 4000) PS to measure FEV₁, forced expiratory volume in 6 seconds (FEV₆), and FEV₁/FEV₆ ratio. We used maximum values for FEV₁ and FEV₆ obtained from the repeated forced expiratory manoeuvres to measure the FEV₁/FEV₆ ratios and a ratio of FEV₁/FEV₆ < 0.7 obtained by the pocket spirometry was considered as the criteria for airflow limitation.¹⁷ We measured the acceptability of the forced expiratory manoeuvre by using the GOLD criteria (ie the two highest values of FVC and FEV₁ from acceptable manoeuvres are within 0.15L).⁴ Trained researchers used the NDD EasyOne portable spirometers (EasyOne, NDD Medical Technologies, Zurich,

Switzerland) as the diagnostic quality spirometer which meets American Thoracic Society (ATS)/European Respiratory Society (ERS) standards (Website: www.ndd.ch).

Training of Community Health Workers

Twenty CHWs were trained to administer the LFQ and conducting PS. Each CHW participated in a pre-testing session with at least 10 participants under the supervision of the research staff. CHWs were shown a video of PS recommended by the manufacturers. During the training, the emphasis was placed on how to coach and encourage the participant to perform an acceptable forced expiratory manoeuvre and to recognize an unacceptable forced expiratory manoeuvre. Additionally, CHWs were trained to identify people with any contraindication to performing the spirometry using a checklist. After the training, eight out of 20 CHWs were selected to conduct the PS after ascertaining their ability to use the PS.

Study Procedures

CHWs screened all eligible individuals who consented to take part in the study using a paper-based version of the LFQ in participants' homes during September and October 2017. The information from the LFQ was entered into a Microsoft Excel spreadsheet by a data entry operator and data were checked for any inconsistencies by a research staff not involved in the screening process. Primary and secondary sample lists of 250 randomly selected participants, each with an LFQ score of ≤ 18 or > 18 were invited for assessing their height and weight at nearby community halls of their respective villages. Height was measured in cm to the nearest 0.1 cm with a portable stadiometer and weight was measured to the nearest 100 gm with a reliable weighing scale in light clothes with no shoes in a standardised manner. After ruling out contraindications for spirometry using a checklist, PS was conducted by CHWs. The trained researchers then conducted pre and post-bronchodilation (BD) spirometry using the diagnostic quality spirometers. Study participants rested for 15–20 minutes between PS and diagnostic spirometry and also between pre and post-BD spirometry. CHWs performing PS were blinded to the LFQ scores and trained researchers were blinded to the LFQ scores and the PS results. Standards for Reporting Diagnostic accuracy studies (STARD) were used to report the findings of the study ([Table S1](#)).¹⁸

Statistical Analysis

The sample size calculation was based on the assumption that a random sample of 130 participants from the positive population (LFQ score ≤ 18) and 130 (LFQ score > 18) from the negative population would produce an AUC of 0.75 (95% CI: 0.63 to 0.87).¹⁹

Baseline characteristics of participants were compared using independent *t*-test and Pearson's chi-square statistics. Diagnostic accuracy was measured by determining the sensitivity, specificity, AUC, positive and negative likelihood ratios, and predictive values of the individual test (LFQ and PS) and the combined sequential strategy (PS conducted among those with LFQ score ≤ 18). Bland-Altman (B&A) plots were used to describe the agreement between the two measurements of the maximum values for FEV₁ obtained by PS and pre-bronchodilation spirometry, using the diagnostic quality spirometer and maximum values of FEV₆, FVC measured respectively by the PS and pre-bronchodilation spirometry. Finally, we conducted a sensitivity analysis by measuring the diagnostic accuracy for individual CHWs, the best four performing CHWs (n=4), and the worst-performing CHWs (n=4). All statistical analyses were conducted using the STATA software V.12 (StataCorp, College Station, TX, USA).

Ethical Considerations

The study was conducted in accordance with the Declaration of Helsinki and was approved by the Institutional Ethics Committees of Deakin University and the Public Health Foundation of India. The CHWs obtained written and informed consent from all study participants. Participants diagnosed with COPD were referred to the nearest public health centre for further evaluation and management and were provided risk reduction advice for their risk factors.

Results

The flow of participants who completed the LFQ and subsequently the pocket spirometry and the pre and post-bronchodilator spirometry is shown in [Figure 1](#). For screening, 3256 eligible individuals completed the LFQ, 268 participated in PS and 251 participants completed the post-bronchodilation spirometry ([Figure 1](#)). Twelve participants did not want to undergo further spirometry and lung function test results for five participants was not included in the analysis due to incompleteness of the

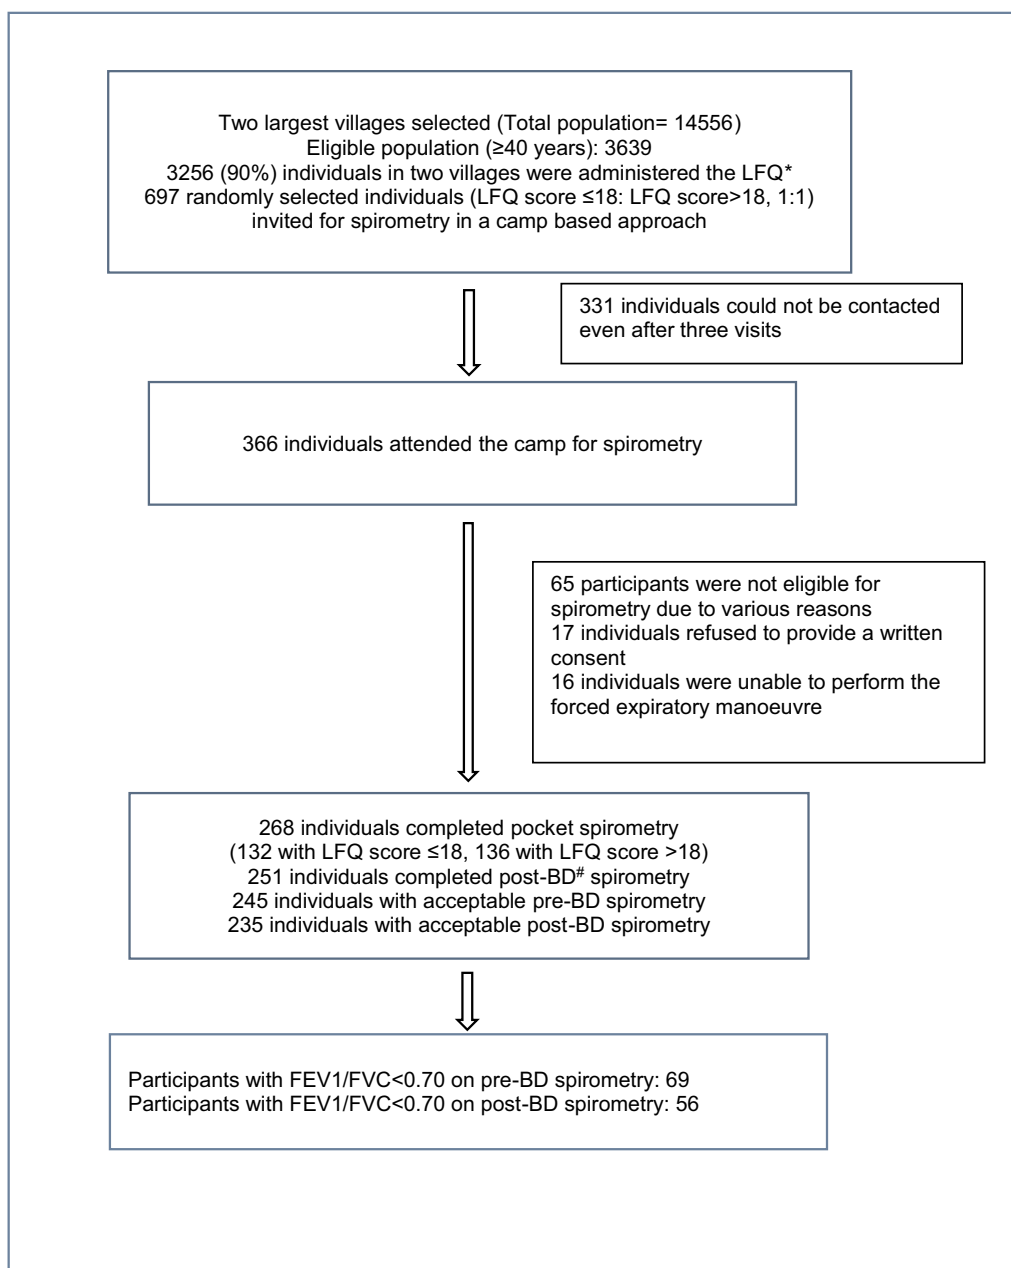

Figure 1 Participant flow diagram.

Abbreviations: LFQ, Lung Function Questionnaire; BD, bronchodilation.

data (results from only one forced expiratory manoeuvre were available for these five participants).

There were no significant differences in the mean age, gender distribution, and proportion of those who were able to read and understand the LFQ between the participants who were randomly selected and those not selected for spirometry. The mean LFQ score of the participants who participated in spirometry was slightly lower than the total LFQ score of the participants who were not selected for spirometry (Table 1).

There were no significant differences (>150mL) in the group mean values for FEV₁ and FEV₆ volumes between the three acceptable blows recorded using the PS (Table 2). However, a difference of >150 mL between an individual participant's two highest FEV₁ volumes was present in 60 (22.4%) measurements and a difference of >150 mL between the two highest FEV₆ volumes was present in 92 (34.3%) measurements.

The mean (±SD) difference between FEV₁ and between FEV₆ and FVC measured by PS and pre-BD spirometry

Table 1 Comparison of Demographic Characteristics of the Study Participants (N=3256)

Variables	Participants without Spirometry (n=2988)	Participants Randomly Selected for Spirometry (n=268)	p-value
Mean age in years (\pm SD)	56.5 (\pm 12.2)	56.7 (\pm 10.4)	0.83

Table 2 Comparison of Lung Function Parameters (FEV₁ and FEV₆) of Participants Obtained from the Three Best Forced Expiratory Manoeuvres on the Pocket Spirometer

Parameters N = 268	FEV ₁ Blow 1	FEV ₁ Blow 2	FEV ₁ Blow 3	FEV ₆ Blow 1	FEV ₆ Blow 2	FEV ₆ Blow 3
Mean	1.57	1.63	1.65	2.14	2.26	2.23
Standard deviation	0.68	0.67	0.67	0.83	0.90	0.80
Range	0.38–3.77	0.42–3.86	0.39–3.95	0.57–4.81	0.51–7.58	0.66–4.71

respectively was 105 mL (95% CI: 81–130 mL) mL and 156 mL (95% CI: 102–211 mL) respectively (Table 4) and 67% of FEV₁ values measured by PS had a difference of fewer than 150 mL as compared to FEV₁ measured by pre-BD spirometry (Table 3).

The prevalence of COPD in the study population was 23.8% (95% CI: 18.3–28.8). Among participants who underwent pre-BD diagnostic level spirometry with acceptable manoeuvres (n=235), 69 (29%) had an airflow limitation (FEV₁/FVC<0.70). Based on post-BD diagnostic level spirometry with acceptable manoeuvres (n=235), 56 (24%) met criteria for COPD diagnosis with 9 participants (16%) diagnosed with GOLD Stage 1, 32 (57%) with Stage 2, 12 (21%) with Stage 3 and 3 (5%) with Stage 4 COPD severity.

The sensitivity of the LFQ was higher (75%, 95% CI: 61.6%–85.6%) than the PS (69.6%, 95% CI: 55.9%–81.2%), while the specificity of PS was higher (81.0%, 95% CI: 74.5%–86.5%) than the LFQ (55.3%, 95% CI: 47.7%–62.7%). The combined sequential strategy had the highest AUC and positive predictive values and positive likelihood ratios. The sequential strategy was able to detect 79% of COPD cases (67% of GOLD Stage 1, 78% of GOLD Stage 2, 82% of GOLD Stage 3, and 100% of GOLD Stage 4 of airflow limitation).

The Bland-Altman plot showed fewer differences (n=6/245 >2SD) between the two devices when comparing FEV₁/FEV₆ ratio with the FEV₁/FVC ratio (Figure 2, Panel 1).

Sensitivity Analysis

Eight CHWs conducted spirometry with the PS, one CHW was not able to conduct spirometry and was discontinued after conducting spirometry on three participants. The diagnostic accuracy of the sequential strategy increased

when we restricted the analysis to the four best performing CHWs in PS [sensitivity: 92.9% (76.5%–99.1%); specificity: 75.5% (61.7%–86.2%)], as compared to the other four CHWs [sensitivity: 50.0% (23.0%–77.0%); specificity: 85.2% (66.3%–95.8%)]. Almost all CHWs except one were able to detect participants with COPD GOLD severity stages 3 and 4 (Supplementary Table S2).

Discussion

Early detection of COPD is necessary to accurately determine the actual disease burden and initiate appropriate therapies to reduce mortality, limit disability, and improve quality of life. In this study, we found that a sequential screening strategy implemented by CHWs using an LFQ followed by PS was highly sensitive and specific in detecting adults with COPD in a rural community of North India. Notably, this sequential strategy was able to detect over four-fifths of severe and very severe (GOLD Stage 3 and GOLD Stage 4) COPD cases.

Most studies evaluating COPD screening using a questionnaire in primary care have been conducted in high-income countries.^{8–11} A recent systematic review of the evidence regarding COPD screening reported that the COPD Diagnostic Questionnaire (CDQ) was the best screening questionnaire.²⁰ However, we used the LFQ as a screening tool because LFQ includes a question about smoking in general as compared to other questionnaires including CDQ that specifically ask about cigarette smoking. As other forms of tobacco smoking are common in the Indian population, the LFQ was deemed to be a more appropriate screening questionnaire for our study. We found that the diagnostic accuracy values of LFQ and pre-BD PS in measuring FEV₁/FEV₆ in our study were similar to values reported by the use of other screening

Table 3 Diagnostic Performance of the Lung Function Questionnaire (LFQ), Pocket Spirometry (PS) and the Combined Strategy (LFQ Followed by the PS) Compared to the Post-Bronchodilation Spirometry (n=235)

Parameters	Lung Function Questionnaire	Pocket Spirometry	Combined
Prevalence, % (95% CI)	24 (19.0–29.8)	24 (19.0–29.8)	34.0 (26.0–43.6)
Sensitivity, % (95% CI)	75.0 (61.6–85.6)	69.6 (55.9–81.2)	78.6 (63.2–89.7)
Specificity, % (95% CI)	55.3 (47.7–62.7)	81.0 (74.5–86.5)	78.8 (68.2–87.1)
Area under the receiver operating characteristics curve	0.65 (0.58–0.72)	0.75 (0.69–0.82)	0.79 (0.71–0.86)
Likelihood ratio (+)	1.68 (1.34–2.10)	3.67 (2.59–5.19)	3.70 (2.36–5.80)

Notes: *FEV₆ for pocket spirometry, FVC for gold standard spirometry.

questionnaires and hand-held pulmonary function screening tests.²⁰

A few studies have assessed the diagnostic accuracy of using a screening questionnaire followed by an assessment of lung function using pocket spirometers/flow meters.

Sichletidis et al in Greece found that a combination of the International Primary Care Airways Guidelines questionnaire (IPAG) and use of the PiKo-6 flow meter by general practitioners (GPs) had a higher sensitivity (72%) and specificity (97%) than individual use of the IPAG

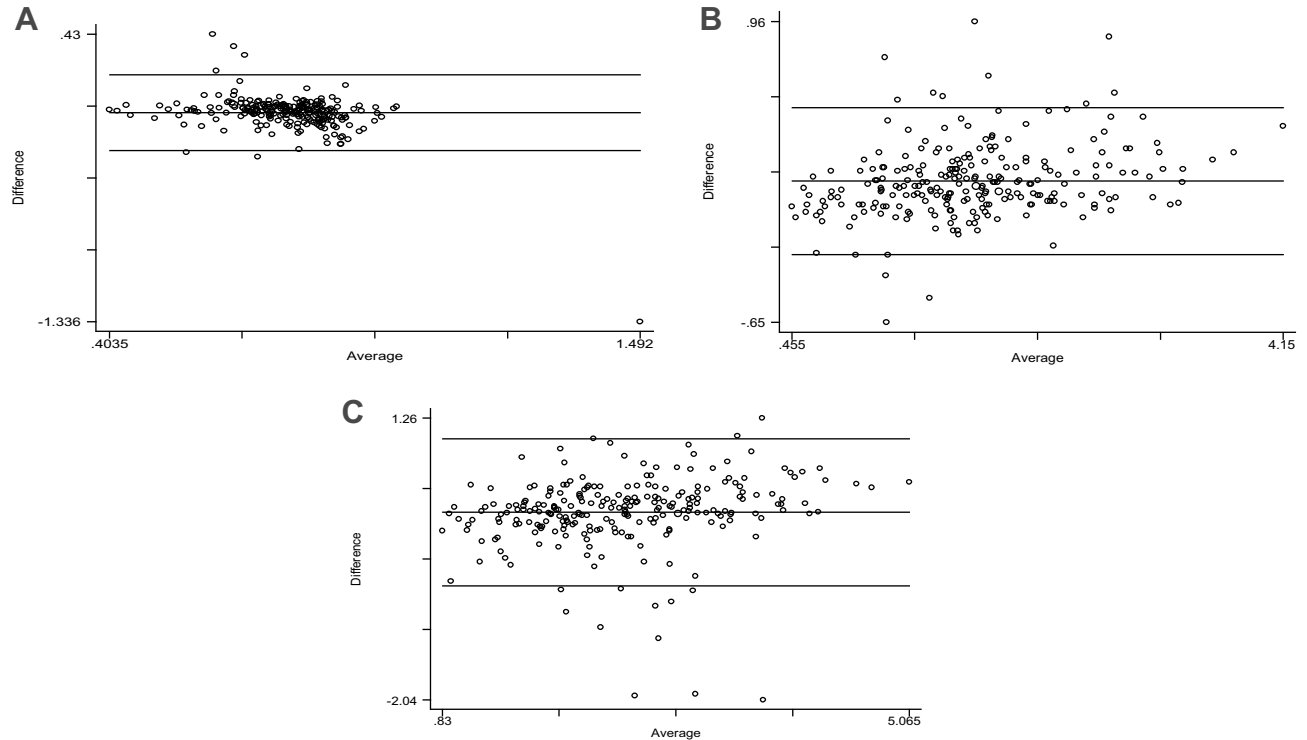

Figure 2 Bland-Altman plots comparing lung function parameters between pocket spirometry and pre-bronchodilator spirometry. **(A)** Bland-Altman plot comparing FEV₁/FEV₆ ratio obtained from pocket spirometry with that FEV₁/FVC ratio of pre-bronchodilator spirometry **(B)** Bland-Altman plot comparing FEV₁ obtained from pocket spirometry with that of pre-bronchodilator spirometry. **(C)** Bland-Altman plot comparing FEV₆ obtained from pocket spirometry with that of FVC obtained from pre-bronchodilator spirometry.

(sensitivity: 80% and specificity: 95%) and flow meter (sensitivity: 91% and specificity: 49%).²¹ The specificity of the combined tests was lower in our study (78.8%) as compared to the study (95%) by Sichletidis et al.² In our study, the readings obtained for forced expiration manoeuvres (FEV₁ and FVC values) using diagnostic quality spirometry by trained researchers were higher than those obtained by CHWs using PS. This possibly also reflects that participants had gained experience after performing the required forced expiratory manoeuvres using the PS and that better coaching of participants by trained researchers to perform the maneuver was possible because they could see the flow-volume curves on their computer screens. This indicates that the diagnostic accuracy of the test also depends upon the skills of those performing the spirometry and the ability of participants to understand and perform the manoeuvre. Despite this, for the majority of participants, the differences between FEV₁ values measured between two devices was less than 150 mL.

Fujita et al found improved detectability of COPD in primary care settings using a hand-held flow meter regardless of the use of a symptom-based questionnaire.¹¹ This may preclude the use of the screening questionnaire allowing screening of the population using PS alone.¹¹ However, Franco-Marina et al, found that although the PS alone using a cut-off point of FEV₁/FEV₆ <0.80 had a marginally better test performance, the sequential strategy had a sensitivity of 75%-80% and a specificity of around 85%.¹⁷ Besides, the use of a screening questionnaire reduced the number of individuals who needed screening using spirometry. This is an important consideration in low resource settings like rural India, where health infrastructure is constrained. Based on the findings from our study, administration of the LFQ reduced the workload for CHWs related to conducting PS by about 60%, increasing the feasibility and sustainability of a potential community-based screening program.

Some studies have reported on the accuracy of screening with a questionnaire in combination with a peak flow meter.²²⁻²⁵ However, the reliability of the peak flow meter in detecting COPD has been questioned.²⁶ A systematic review conducted by Haroon et al found that PS is useful for COPD screening in primary care settings justifying its use in the current study.²⁷

US Preventive Services Task Force did not find any conclusive evidence for the benefit or harm of screening asymptomatic adults with questionnaires or office-based

spirometry.²⁰ However, the GOLD guideline advocates the use of spirometry among those with symptoms and risk factors for early detection and the use of risk-score based screening questionnaires for screening in primary care settings.⁴ The evidence for the utilization of screening with questionnaires and PS as a preliminary detection or case-finding method is sparse, especially from LMICs. Implementation of spirometry requires its correct performance, reliable interpretation, and regular calibration of spirometers.²⁸ These are very challenging criteria to meet especially in resource-constrained settings of LMICs like India, where the burden of COPD is high. Therefore, our study demonstrates a feasible approach to improve early detection and referral to ensure timely management, potentially resulting in improved disease outcomes. It also provides insights to obtain robust and reliable data to determine the actual COPD burden.

Currently, the National Programme for Prevention and Control of Diabetes, Cardiovascular Disease and Stroke (NPCDCS) in India, which also addresses the prevention and management of COPD, envisages that CHWs, ie, Accredited Social Health Activists (ASHA), will complete a score-based checklist, entitled Community Based Assessment Checklist (CBAC), through household visits.²⁹ The CBAC is supposed to be reviewed by an Auxiliary Nurse Midwife at a sub-centre (first point of contact for rural populations with non-physician health care providers in the Indian public health care system). Those with a high risk for non-communicable diseases (NCDs) are then referred to the primary health centre (first point of contact for rural populations with physician health care providers) for confirmation of the diagnosis and management. Our study has shown that CHWs can be trained to detect COPD at the community-level using a risk-score-based questionnaire and a pocket spirometer. However, underutilization of spirometry for the diagnosis of COPD, especially among physicians other than chest physicians in India, necessitates the strengthening of the infrastructure both in public and private health sectors to confirm diagnoses through spirometry.⁵ There is a need for further effectiveness and implementation research to assess the potential health benefits that can be achieved by this screening strategy for screening COPD at village level and sub-centre with subsequent linkage to the primary and secondary health care infrastructure for confirmation of diagnosis with post-bronchodilation spirometry for COPD management.

To our knowledge, this is one of the first studies that assesses the diagnostic accuracy of utilizing CHWs to detect individuals with COPD using a screening questionnaire and PS in the community. However, increased detection of COPD should also be supported by strengthening the health systems to enable the confirmation of diagnosis and provision of timely guideline-based management, especially inhalational drugs in primary and secondary health care facilities.

This study had some limitations also. Due to limited resources, we could not perform our study on a larger sample, which limited the statistical power of the study to assess differences in the performance of individual CHWs in conducting PS. A few severe cases were missed by CHWs, however, all missed cases were participants who could not read or understand instructions clearly and it was thus difficult for the CHWs to coach these participants to perform the forced expiratory manoeuvres optimally. Additionally, we did not assess the exposure to the biomass fuel smoke as it was not part of the validated LFQ. Exposure to biomass fuel is one of the common risk factors for development of COPD especially among women in rural areas of LMICs. There is a need to develop a risk-score based screening questionnaire with a component of biomass fuel smoke exposure assessment and also assess its validity in detecting COPD.

Conclusion

In conclusion, undiagnosed COPD can be accurately identified by trained CHWs using a simple sequential screening strategy. This can potentially contribute to an accurate assessment of COPD burden and also to design tailored interventions for its effective management in rural India. More studies with a larger sample size in similar settings are required to further evaluate the feasibility, scalability, and sustainability of this sequential screening strategy to improve the early detection of COPD in low-resource settings.

International Journal of Chronic Obstructive Pulmonary Disease

Dovepress

Publish your work in this journal

The International Journal of COPD is an international, peer-reviewed journal of therapeutics and pharmacology focusing on concise rapid reporting of clinical studies and reviews in COPD. Special focus is given to the pathophysiological processes underlying the disease, intervention programs, patient focused education, and self management

protocols. This journal is indexed on PubMed Central, MedLine and CAS. The manuscript management system is completely online and includes a very quick and fair peer-review system, which is all easy to use. Visit <http://www.dovepress.com/testimonials.php> to read real quotes from published authors.
