**Background:** Besides their clinical significance in blood transfusion medicine, ABO and Rh blood group antigens were found to be associated with many non-infectious and infectious diseases. This investigation aimed to assess the association of ABO and Rh blood group antigens with transfusion transmissible infections (TTIs).

**Methods and Materials:** A cross-sectional retrospective investigation was conducted on 27,027 blood donors at Bahir Dar blood bank, from March 24/2019 to October 21/2021. The blood sample was collected from each blood donor and tested for TTI markers (HBV, HCV, HIV, and syphilis), with ELISA, and ABO and Rh blood grouping was performed. Descriptive analysis was done for sociodemographic data, and a chi-square test was used to show the association between the ABO and Rh blood groups with TTI markers, and a P-value <0.05 was considered statistically significant.

**Results:** From 27,027 study participants, 18,911 (70%) were males, with a mean age of 25.2 years, and 49.4% of the blood donors were students. The overall TTI prevalence was 5.43%, of which 2.8% was HBV, 1.5% was syphilis, 0.8% was HIV, and 0.3% was HCV. Blood group O (41.4%) was the most common blood group followed by, A (29.6%), B (23.6%), and AB (5.4%). Ninety-one point seven percent of the blood donors were Rh (D) positive. All TTI markers (HBV:  $p = 0.62$ , HIV:  $p = 0.77$ , HCV:  $p = 0.52$ , and syphilis:  $p = 0.94$ ) showed no significant association with ABO blood group. Rh blood type also showed no association with all TTI markers.

**Conclusion:** The prevalence of TTI markers was not significantly associated with ABO and Rh blood groups.

**Keywords:** ABO and Rh blood groups, blood donors, transfusion transmissible infections

## Introduction

The surface of red blood cells (RBCs) contains different blood group antigens made up of polysaccharides and proteins. Along with their expression on red blood cells, ABO blood group antigens are also found on other cells and tissues like epithelium, sensory neurons, platelets, the vascular endothelium, breast ductal and lobular cells, and some malignant cells.<sup>1</sup> Among the blood group antigens identified, ABO and Rhesus (Rh) are the most widely studied. Besides their clinical significance in the blood transfusion and compatibility, ABO and Rh blood group antigens were found to be associated with many non-infectious and infectious diseases.<sup>2,3</sup> Several studies revealed these blood group antigens were associated with diabetes mellitus, hypertension, gastric cancer, duodenal ulcer, breast cancer, malaria, and helicobacter pylori infection.<sup>2,4,5</sup> Some other studies also reported that ABO and Rh blood group antigens were associated with

transfusion-transmitted infections (TTIs), which include Hepatitis B virus (HBV), human immunodeficiency virus (HIV), Hepatitis C virus (HCV), and syphilis.<sup>2,6,7</sup>

Nowadays, the prevalence of TTI is increasing, especially in the developing world. This high prevalence of TTI incurs increased morbidity, mortality, and compromises the quality of life of the world's population. The acquisition of TTIs has become a vital obstacle, worthy of investigation, to maintain both the health and safety of human life.<sup>8</sup>

In Malawi, the prevalence of HBV, HCV, HIV, Syphilis was 3.6%, 1%, 1.9%, 2.6%, respectively, in 2015.<sup>9</sup> A study conducted in Angola also reported even a higher TTI prevalence in which HBV (8.4%) infection covered a larger proportion, followed by syphilis (4.4%), HCV (3%) and HIV (2.1%).<sup>9,10</sup> In Eritrea, the prevalence of HIV, HBV, HCV and Syphilis was 0.8%, 5%, 0.7% and 7.2%, respectively, and in Ethiopia, the overall prevalence of TTI was 6% (HBV = 3.9%, HCV = 0.6%, HIV = 0.5% and syphilis = 1.2%) in 2019.<sup>11,12</sup>

Considering this high prevalence, the World Health Organization (WHO) recommended that, the blood and blood products collected for transfusion should be screened for HIV, HBV, HCV, and syphilis as a minimum requirement.<sup>13</sup> Additionally, strict pre-donation screening and deferral of blood donors with high-risk behaviors is required to ensure safe blood and blood product.

The route of transmission of TTIs is principally through blood and blood products, sharing of needles to inject drugs, needle stick injury, and sexual contact. After their entrance into the host different factors like immune status of the host, load of the infectious agent, and route of transmission contributed to the development of an active infection. In addition to these factors, several studies also disclosed that ABO and Rh blood group antigens were associated with the development of active infection.<sup>14,15</sup> The probable pathogenesis for the link between blood group antigens and disease susceptibility is that many organisms may bind to polysaccharides on the cell surface, but soluble blood group antigens may block this binding. On the other hand, different ABO antigens can prevent the species carrying it from being threatened by a pathogen using a given carbohydrate as a receptor. On the other saying, the ABO polymorphism leads to a polymorphic production of anti-A and anti-B natural antibodies, which potentially protect individuals from several infectious agents expressing A and B antigens.<sup>16</sup>

Several studies were conducted to show the possible link between ABO and Rh blood groups with TTI. For instance, in a study conducted by Tyagi et al, blood group A negative was associated with an increased risk of contracting HIV and HBV infection, while blood group B negative with syphilis.<sup>15</sup> Another study also found maximum TTI sero-reactivity among B blood group donors (2.21%) followed by blood group A donors (2.16%), O donors (1.57%), and AB donors (1.17%), but was not statistically significant.<sup>17</sup> In a study conducted in Gabon, no significant association was obtained between the prevalence of HIV, HCV, and syphilis and the ABO and Rh blood groups. However, HBV sero-prevalence was twice as high among non-O blood group donors compared with blood group O donors.<sup>7</sup> A systematic review and meta-analysis study by Jing et al, indicated that blood group B was associated with a lower risk of HBV infection.<sup>14</sup>

Despite the presence of several studies on this project, the findings were not consistent, and as to our understanding, there was no such study conducted in Ethiopia. The lack of such information has initiated us to conduct this investigation. The main objective of this study was to assess the association between transfusion-transmitted infections and the ABO and Rh blood groups. The information obtained will be used by the governmental agencies to set firm blood donor selection criteria, and blood banks to pay attention when they enrolled their blood donors.

## Methods and Materials

A cross-sectional retrospective investigation was conducted on 27,027 blood donors at Bahir Dar blood bank from March 24/2019 to October 21/2021. Bahir Dar blood bank is located in the capital city of Amhara regional state Bahir Dar, Ethiopia. Bahir Dar is found in northwest Ethiopia 565 km away from Addis Ababa, the capital city of Ethiopia.

All blood donors, included in our analysis, were voluntary non-remunerated blood donors. Five milliliters of blood samples were collected from all blood donors, from which tests for TTI markers (HBV, HCV, HIV, and syphilis) and ABO and Rh blood grouping were performed. The serum sample from each blood donor was tested with an enzyme-linked immunosorbent assay (ELISA). HBV surface antigen (HBsAg) and anti HCV antibody (anti-HCV) were tested with third-generation ELISA (wantai, Beijing Wantai Biological Pharmacy, China), HIV 1 and 2 antibodies and antigens

were tested with fourth-generation ELISA (Microlisa, J. Mitra and Co. Pvc. Ltd, India), and anti-Treponema pallidum antibodies were tested with DIALAB Syphilis IgG/IgM ELISA (Dia lab, Austria).

Forward and reverse ABO grouping was performed by slide method with commercially available antisera (anti-A and anti-B) (Mediclone, Mediclone Biotech, India) and by using 5% A and B cell suspension prepared at home, respectively. Rh typing was performed by test tube method with anti-D reagents, and Coombs test was performed to detect weak D antigen (Mediclone, Mediclone Biotech, India).

All donors' data including relevant socio-demographic, TTI marker result, ABO and Rh blood type were registered on the computerized blood donor data management system. Ethical clearance was secured from research ethics committee of Injibara University College of Health Sciences with reference number HSc-350. The data were collected after getting a seal of approval from Bahir Dar blood bank. The data were checked for completeness, and transferred to SPSS version 23 for further analysis.

Descriptive analysis was done for sociodemographic data, and a chi-square test was used to show the correlation between the ABO and Rh blood groups with TTI markers, and a P-value <0.05 was considered statistically significant. Bonferroni post hoc test was performed to detect which cells from the contingency table were significantly different.

The data were collected after getting acquiescence from the blood bank, and we used only donor ABO and Rh blood group, age, sex, and occupation based on the code given at the blood bank. Other than these we did not use other voluntary blood donor data like name and phone number. All the data were secured, protected, and accessible only to the investigators.

## Results

Of 27,027 study participants, 70% were males, and 58.5% were within 18–24 years age range (Table 1). The minimum and maximum ages were 18 and 67 years, with a mean age of 25.2 years, and 49.4% of the blood donors were students (Table 2). Blood group O (41.4%) was the most prevalent blood group followed by A (29.6%), B (23.6%), and AB (5.4%). Ninety-one point-seven percent of the blood donors were Rh (D) positive (Table 3). Of 27,027 blood donors, 1469 (5.4%) were positive at least for one of the TTI markers, from which HBV accounts 2.8% (767), syphilis 1.5% (402), HIV 0.8% (207) and HCV 0.3% (93) (Table 4).

## Association of ABO and Rh Blood Group with TTI Markers

In this study, out of the 767 HBV positive cases, O (41.6%) was the most frequent blood group followed by A (29%), B (23%), and AB (6.4%). Among 207 HIV positive cases, blood group O (42.5%) blood donors were the most predominant succeeded by blood group A (27.5%), B (25.6%), and AB (4.4%). Of 93 HCV positive individuals, those with blood group O (46.2) were predominant followed by A (31.2%), B (17.2%), and AB (5.4%), and among 402 Syphilis reactive donors O (42.3%) blood group was predominant, followed by A (28.4), B (24.1%), AB (5.2%) blood group individuals. In HBV, syphilis, HIV, and HCV reactive case, 9.1%, 6.9%, 7.7%, and 11.8%, respectively, were Rh-negative (Table %).

Even though it was not statistically significant ( $X^2 = 1.78$ ,  $p = 0.62$ ), this study revealed the highest prevalence of HBV case in blood group AB. Blood groups B and O were found to have equally higher prevalence of HIV ( $X^2 = 1.12$ ,  $p = 0.77$ ). Relatively higher prevalence of HCV was seen in A and O blood groups ( $X^2 = 2.24$ ,  $p = 0.52$ ), but B and O blood groups were considered as having equally higher prevalence of syphilis ( $X^2 = 0.37$ ,  $p = 0.94$ ). Higher prevalence of HBV

**Table 1** Age and Sex Distribution of Study Participants

Sex	Age Range						Total
	18–24	25–29	30–34	35–39	40–44	≥45	
Female	6442	871	337	227	123	116	8116 (30%)
Male	9377	3647	2951	1475	739	722	18,911 (70%)
Total	15,819 (58.5%)	4518 (16.7%)	3288 (12.2%)	1702 (6.3%)	862 (3.2%)	838 (3.1%)	27,027 (100%)

**Table 2** Occupational Distribution of Study Participants

Occupation	Frequency	%
Civil servant	5658	20.9
Private worker	5171	19.1
Student	13,361	49.4
Unemployed	2128	7.9
Others	709	2.6
Total	27,027	100

**Table 3** ABO and Rh Blood Group Distribution of Study Participants

Rh	ABO				Total
	A	AB	B	O	
Negative	695 (2.6%)	126 (0.5%)	478 (1.8%)	941 (3.5%)	2240 (8.3%)
Positive	7315 (27.1%)	1324 (4.9%)	5908 (21.9%)	10,240 (37.9%)	24,787 (91.7%)
Total	8010 (29.6%)	1450 (5.4%)	6386 (23.6%)	11,181 (41.4%)	27,027 (100.0%)

and HCV were seen among Rh-negative blood donors, while HIV and syphilis positivity rate was higher among Rh-positive blood group donors (Table 4).

## Discussion

The relationship between ABO and Rh blood groups and numerous diseases has been investigated extensively by different scholars. The current study was conducted to show the association between TTIs (HBV, HCV, HIV, and syphilis) and ABO and Rh blood group antigens. On the current topic, several studies have been conducted, some of them reported a link between ABO and Rh blood types and TTIs,<sup>2,14</sup> while others testified no significant association.<sup>17,18</sup> In the current study the TTI prevalence was 5.4%, with HBV (2.8%) being the most prevalent, followed by Syphilis (1.5%), HIV (0.8%) and HCV (0.3%). Our finding was comparable with the output of studies conducted by Shiferaw et al,<sup>11</sup> Biadgo et al<sup>19</sup> and Arif et al<sup>6</sup> but relatively lower than the prevalence reported by Peliganga et al<sup>10</sup> and higher than that of Prakash et al<sup>17</sup> and Hroob et al.<sup>8</sup> The observed difference in the prevalence of TTI markers may be due to differences in lifestyle and economic status of the study participants.

**Table 4** Association of ABO and Rh Blood Group with TTI Markers

ABO	HBV		HCV		HIV		Syphilis	
	Negative (n, %)	Positive (n, %)	Negative (n, %)	Positive (n, %)	Negative (n, %)	Positive (n, %)	Negative (n, %)	Positive (n, %)
A	7788 (97.2)	222 (2.8)	7981 (99.6)	29 (0.4)	7953 (99.3)	57 (0.7)	7896 (98.6)	114 (1.4)

	$\chi^2 = 0.73, p = 0.39$				$\chi^2 = 0.086, p = 0.77$		$\chi^2 = 0.94, p = 0.33$	

**Abbreviations:** HBV, hepatitis B virus; HIV, human immunodeficiency virus; HCV, hepatitis C virus.

In this study, even though it was not significant ( $p=0.62$ ), the highest prevalence of HBV was found in blood group AB, whereas the lowest positivity rate was in blood groups A and B. Similarly, studies conducted by Prakash et al<sup>17</sup> and Sreedhar Babu et al<sup>18</sup> revealed no association between TTI markers and ABO blood groups. However, a study carried out by Liu et al<sup>2</sup> revealed the presence of a significant association between ABO blood group and the risk of TTI, in which blood group O was associated with an increased HBV infection rate. In the current investigation, blood groups B and O were found to have the highest prevalence of HIV and syphilis, but the association was not statistically significant. This finding was in concordance with a study conducted by Ngassaki-Yoka et al,<sup>7</sup> which detected no association between ABO blood group and TTIs. Even though it was not significant, a comparatively higher frequency of HCV positivity was seen among A and O blood group donors. This discrepancy might be caused by characteristics of the study participants and the differences in blood type frequency distribution in different ethnic groups.<sup>2</sup>

This study also testified that Rh (D) type was not associated with all TTI markers' positivity rate. In line with our finding, investigations done by Bharadva et al<sup>20</sup> and Sreedhar Babu et al<sup>18</sup> found no association, but the existence of a significant association was reported by Liu et al,<sup>2</sup> in which Rh-D-positive participants were at higher risk of HBV infection.

## Conclusion and Recommendation

The main aim of this research work was to show the prevalence of TTI (HBV, HCV, HIV, and syphilis) and its association with ABO and Rh blood groups. According to our findings, the prevalence of TTI was not significantly associated with ABO and Rh blood group phenotypes.

## Data Sharing Statement

All relevant data are included in this document.

## Ethical Considerations

Ethical clearance was obtained from research ethics committee of Injibara University College of Health Sciences with reference number HSc-350. A permission letter was obtained from Bahir Dar blood bank. Since it was a retrospective analysis, written informed consent was not obtained from each study participant. To safeguard confidentiality, all blood donor data were collected after removing all personal identifiers by the blood bank data manager.

## Consent for Publication

Consent for publication of this work was found from Bahir Dar blood bank.

## Acknowledgment

Authors' deepest gratitude goes to Bahir Dar blood bank staff for their cooperation during the data collection.

## Author Contributions

All authors made a significant contribution to the work reported, whether that is in the conception, study design, execution, acquisition of data, analysis and interpretation, or in all these areas; took part in drafting, revising or critically reviewing the article; gave final approval of the version to be published; have agreed on the journal to which the article has been submitted; and agree to be accountable for all aspects of the work.

## Disclosure

The authors have declared that no competing interests exist.
