Objective: This study investigated the knowledge of Saudi mothers regarding the management of traumatic dental injuries (TDIs) in children.

Materials and methods: A cross-sectional study using structured questionnaires was employed for mothers chosen by stratified-cluster random sampling technique from primary health care centers in Riyadh, Saudi Arabia, over a period of 12 months (July 2016–June 2017). The questionnaire surveyed mothers' background and knowledge on management of tooth fracture and avulsion using photographs of TDI cases.

Results: The sample consisted of 3,367 Saudi mothers. More than half of the mothers (55.3%) gave the correct response, which was to send the child with tooth fracture immediately to the dentist ($p < 0.01$). The majority of mothers (41.6%) gave the correct response for the immediate mode of action, which was to save the avulsed tooth in storage medium and send the child to the dentist immediately ($p < 0.001$). However, they prioritized the immediate management of TDIs, and most reported saline as a suitable storage medium ($p < 0.001$). The mothers expressed a positive interest in further education.

Conclusion: Educational programs and TDI protocols must be implemented to increase mothers' awareness and improve the prognosis of children with TDIs.

Keywords: mothers, knowledge, traumatic dental injuries

Introduction

One of the most common dental problems seen in children is injury to both primary and permanent dentition and supporting structures, typically caused by accidental falls.^{1,2} Such injuries are disturbing experiences that affect both children and the parent or caregiver, whose ability to manage such problems requires adequate understanding, the immediate exercise of judgment, and prompt action. Both the parent or caregiver (through their prompt response) and the pediatric dentist who sees the child play an important role in restoring oral and emotional health. The management of these children is perhaps unmatched by any other segment of dental practice.^{3,4} Furthermore, execution of proper advice and correct immediate management by mothers present at the accident site will strongly affect the prognosis of such traumatic dental injuries (TDIs).

In response to a lack of adequate awareness and management skills, it has been widely advocated to educate both caregivers and people who are in close proximity to accident sites.^{5,6} Children are likely to spend about 60% of their time at home rather than in school or at the playground.⁷ Accordingly, it is important to consider the mother of the injured child, in most cases, as the first person to attend to the child and

make decisions. Even when an accident occurs in a school environment, it is the responsibility of the school authorities to inform the parent of the accident; in such cases, adequate knowledge of how to address such situations on the part of both the school personnel and the parent can substantially reduce the stress of a TDI. The results of a cross-sectional study conducted in Abha, Saudi Arabia, revealed that the surveyed parents had a poor understanding of avulsion;⁸ that said, the study had a small sample size and did not take socioeconomic characteristics into account. Thus, the aim of this study was to investigate, by means of a structured questionnaire, the knowledge of Saudi mothers regarding the management of TDIs in children.

Materials and methods

The study protocol and consent form were approved by the Research and Ethics Committee of Human Studies at the College of Dentistry Research Center (FR 0399) of King Saud University, Saudi Arabia. The sample consisted of 3,367 Saudi mothers who attended primary health care centers in Riyadh, Saudi Arabia, over a period of 12 months (July 2016–June 2017). Most Saudi mothers are required to attend these centers for pregnancy follow-ups, regular checkups for infants and children, and vaccinations.

A stratified-cluster random sampling technique was used to select the required sample. The city of Riyadh was divided into 5 regions. The study sample was recruited from mothers attending 3 primary health care centers in each region that were randomly selected from the list of primary health care centers obtained from the Ministry of Health, Saudi Arabia. Each mother received a letter explaining the nature of the study, along with an informed consent form, which was signed and returned before the start of the study. Mothers who agreed to participate in the study received a 4-part self-administered questionnaire with questions concerning sociodemographic data, knowledge, and their assessment of photographs of TDI cases. Prior to conducting the study, a permission letter was obtained from the author and publisher of the textbook *Essentials of Traumatic Injuries to the Teeth: A Step-by-Step Treatment Guide* to utilize TDI photos in this study.⁹

The questionnaire was pretested in a pilot survey among 30 randomly selected mothers who were not included in the main study. The mothers were asked to complete the questionnaire on 2 occasions separated by 1 week. The questionnaire was found to be suitable for application among the study population, as there was a high concurrence with the answers to the questions on both occasions. Cronbach's α was applied for the reliability of the questionnaire and was found to be 0.82.

The data obtained from the questionnaires were manually entered into the Statistical Package for the Social Sciences (SPSS version 20; IBM Corporation, Armonk, NY, USA) and analyzed at a significance level of $P < 0.05$. The Chi-square test was used to identify differences in responses for different variables.

Results

A total of 3,984 questionnaires were distributed to Saudi mothers, 3,367 of which were completed and returned giving a response rate of 84.5%. The mean (\pm SD) age of the mothers was 32 ± 9.58 years. The majority of the mothers were between 25 and 35 years of age (41.7%) and had a college-level education (67.9%), as presented in Table 1.

The responses to part II of the questionnaire are presented in Table 2, which concerns questions related to the mothers' awareness and knowledge of TDIs. Most of the mothers had not attended a training course (70.7%) or previously received any information about TDIs (63.9%).

Part III of the questionnaire addressed 2 case scenarios with the help of clinical photographs, as described in Table 3. The first scenario involved an 11-year-old child who had fallen and broken an upper front tooth (Figure 1). The second scenario involved a 9-year-old child who had fallen and had an upper front tooth knocked out (Figure 2). In the first case scenario, the majority of the mothers (55.3%) gave the correct response, which was to "send the child immediately to the

Table 2 Responses to part II: awareness and knowledge regarding TDIs of the respondents

Question	Total, N=3,367, n (%)
Q1. Have you witnessed any TDIs in the past?	
Yes	1,822 (54.0)
No	1,545 (46.0)
Q2. Have you ever attended a TDIs education course?	
Yes	987 (29.3)
No	2,380 (70.7)
Q3. Have you obtained information about TDIs previously?	
Yes	1,216 (36.1)
No	2,151 (63.9)
Q4. If yes, source of information:	
Dentist	1,616 (48.0)
Physician	269 (8.0)
Friend	340 (10.1)
Internet/social network	974 (28.9)
Other	168 (5.0)

Abbreviation: TDI, traumatic dental injury.

dentist," while almost half of the mothers (46.1%) believed it was not necessary to save the broken piece of tooth, and this was statistically significant ($p<0.01$ and $p<0.05$, respectively).

In the second case scenario, the majority of mothers (41.6%) gave the correct response for the immediate mode of action, which was to "save the knocked-out tooth in storage medium and send the child to the dentist immediately" and to "immediately replant the knocked-out tooth" (46%), and this was statistically significant ($p<0.001$). A statistically significant difference was observed in the storage medium most suitable for storing the knocked-out tooth reported by nearly one-third of the mothers (31.8%) as normal saline ($p<0.001$). However, 42.9% of the mothers incorrectly responded that the knocked-out tooth was most likely a baby tooth, and this result was statistically significant ($p<0.01$).

The final part of the questionnaire assessed the mothers' interest in managing and learning more about TDIs. The mothers were not confident in their ability to manage a TDI, with the majority (64.3%) admitting that they would be incapable of doing so, and most were willing to receive further information about TDIs (83.9%) as presented in Table 4.

Discussion

This cross-sectional study was conducted to investigate the level of knowledge of Saudi mothers regarding management of TDIs in children. The majority of the mothers surveyed were of childbearing age, between 25 and 35 years of age (41.7%), had a college education (67.9%), and were

Table 3 Responses to part III: case scenarios

Question	Total, N=3,367, n (%)
Case I: an 11-year-old child fell and broke an upper front tooth (Figure 1):	
Q1. Should the broken piece of the tooth be saved?	
a. Yes	1,043 (31.0)
b. No	1,552 (46.1)*
c. I don't know	772 (22.9)
Q2. Immediate action should be:	
a. Send the child immediately to the dentist	1,862 (55.3)**
b. Put the child to bed	1,252 (37.2)
c. I don't know	253 (7.5)
Case II: a 9-year-old child fell down and the upper front tooth got knocked out (Figure 2):	
Q1. What will be your immediate action?	
a. Replant the tooth and send the child to the dentist	387 (11.5)
b. Save it in storage medium and send the child to the dentist	1,401 (41.6)***
c. Stop the bleeding and have the child rest	929 (27.6)
d. Not sure what to do	650 (19.3)
Q2. The knocked-out tooth is likely to be:	
a. Baby tooth	1,447 (42.9)**
b. Permanent tooth	1,112 (33.0)
c. I don't know	808 (24.1)
Q3. Which storage medium is suitable for storing the knocked-out tooth?	
a. Tap water	751 (22.3)
b. Antiseptic solution	303 (9.0)
c. Tissue paper	636 (18.9)
d. Milk	606 (18.0)
e. Normal saline	1,071 (31.8)***
Q4. How soon should the knocked-out tooth be replanted?	
a. Immediately	1,549 (46.0)***
b. Within 30 minutes	498 (14.8)
c. Within a few hours	848 (25.2)
d. By the next day	472 (14.0)

unemployed (74.3%). The latter implies the majority of mothers were available to their children at all times at home and were available to provide first aid if an unfortunate incident of dental trauma were to occur.

Fifty-four percent of the mothers admitted having witnessed TDIs in the past. This is comparatively lower than that reported in the study among mothers in the United Arab Emirates.¹⁰ In this study, a majority of the mothers (70.7%) had not attended any formal training course about TDIs, and 63.9% had not previously received any information about TDIs. Despite their lack of training, Saudi mothers were aware of the importance of immediately treating TDIs, unlike the UAE mothers.¹⁰ An Indian study reported that most of the

mothers surveyed were college graduates and were aware of the emergency management of TDIs regardless of whether they were employed.¹¹

Part III of the questionnaire addressed 2 case scenarios likely to be faced by mothers at home which were presented as simple, concise, and closed-ended questions. Several studies in the dental literature have focused on the parental knowledge of management of avulsion,^{12–14} whereas other

studies have included wider aspects of dental trauma.^{15,16} In most of these studies, the parental knowledge of management of TDIs or only avulsion was deficient, so the need for public awareness of TDIs and their management has been emphasized.

In the first case scenario, which concerned an 11-year-old child who had fallen and broken an upper front tooth, the respondents were unaware of the importance of saving the broken piece of tooth. There are 2 main reasons that the broken piece of tooth must be saved and taken to the dentist with little delay, and this urgency was correctly acknowledged by the majority of the respondents. The most important reason is to ensure that the child has not aspirated the tooth fragment, which would require a chest radiograph to ascertain. Second, it may be possible to bond the tooth fragment to the remaining tooth.

The second case scenario was related to management of an avulsed upper front tooth in a 9-year-old child. The basic knowledge that a 9-year-old child has permanent upper front teeth was correctly answered by only 33% of the mothers; this response is lower than that in a similar study among Jordanian mothers.¹⁷ Although a significantly higher proportion of mothers identified the knocked-out tooth as a baby tooth, which was incorrect, most of the mothers knew that the tooth should be saved in storage medium and that the child should be sent immediately to the dentist for replantation. Although intrinsic factors of each individual may affect the prognosis of traumatized teeth, evidence-based specific storage media are indicated in circumstances where the time period since trauma has been long, such as Hank's balanced salt solution or the tooth rescue box, the latter contains a culture medium comprising amino acids, vitamins, and glucose.¹⁸ However, among the storage media readily available at the time of dental trauma such as milk, water, saliva, or saline, pasteurized milk has been considered most favorable.¹⁹ Furthermore, a study regarding the knowledge of tooth avulsion and its management among dental assistants in Riyadh, which involved a large proportion of females, reported milk to be the best or most suitable storage medium.²⁰ It was assumed that mothers would generally choose milk as the most suitable storage medium, as it is readily available at home, but in this survey, only 18% of the mothers selected milk – most (31.8%) selected saline. This is in accordance with the study conducted among school nurses in which 82% reported saline as the recommended storage medium.²¹

More than 64% of the respondents stated that they were not capable of managing an incident of TDI. Furthermore, more than 83% of the respondents wanted to receive further

information about TDIs, which is encouraging. Certain limitations of this study merits mention in order to improve on future studies. First, being a questionnaire-based survey, there might be some elements of underreporting bias in the study. The cross-sectional study design and nonrespondent bias may be considered as other drawbacks. The knowledge about TDIs among parents, in general, was not investigated. We assumed that majority of the mothers spend more time with their children and play an important role in decision-making, if an incident of TDI was to occur. Therefore, the decision was made to investigate mothers' knowledge regarding TDIs.

The results of this study may help in making strategic plans to enhance the knowledge of mothers about TDIs and its management along with the awareness of long-term consequences following the dental traumatic incident. For instance, oral education programs in the form of seminars, workshops, and distribution of flyers/posters with algorithm for decision-making process may be initiated during pregnancy follow-ups, regular checkups for infants and children, and vaccination appointments.

Conclusion

In general, Saudi mothers lack knowledge of identifying the proper dentition involved in dental trauma, whether a primary or a permanent tooth is involved, and the importance of saving the fractured tooth fragment. These results suggest that there is a need for effective TDI educational programs to be delivered to primary health care centers in Riyadh, which mothers in this survey considered valuable and relevant.
