Abstract: Kabuki syndrome (KS) is an autosomal dominant genetic disorder in which most cases are caused by de novo mutations. KS type 1 is caused by mutations in *KMT2D* (OMIM: #147920) and is more common. KS type 2 is caused by mutations in *KDM6A* (OMIM: #300867). Both genes encode proteins that modify histones and are involved in epigenetic regulation. The enzyme histone-lysine N-methyltransferase 2D, the product of *KMT2D*, is expressed in most adult tissues and is essential for early embryonic development. The main clinical manifestations of KS include dysmorphic facial features, such as elongated palpebral fissures, eversion of the lateral third of the lower eyelids, and short nasal columella with a broad and depressed nasal tip. Additionally, patients also present with skeletal abnormalities, dermatoglyphic features, mild-to-moderate intellectual disability, hearing loss, and postnatal growth deficiency. We describe an 11-year-old girl from Colombia, who presented with characteristic clinical signs of KS. Genetic studies showed a *KMT2D* intronic variant (*KMT2D* NM_003482.3: c.511-2A> T) as a cause of KS.

Keywords: Kabuki syndrome, coloboma, rare disease, RNA splicing, sensorineural hearing loss

Introduction

Kabuki syndrome (KS) is a rare disease of genetic origin, first described in Japan by Niikawa & Kuroki in 1981. Its name is owed to the similarity of the facial dysmorphism characteristic of this condition with the makeup and kabuki masks used in traditional Japanese theater.^{1,2} KS prevalence is 1:32,000 live births in Japan and possibly similar in the rest of the world. In Colombia, the official number of diagnosed cases is unknown. However, 8 cases have been reported. KS does not have a predominance of ethnicity, age, or sex.^{2,3}

This syndrome is characterized by dysmorphic facial features, such as elongated palpebral fissures with eversion of the lateral third of the lower eyelids, arched eyebrows, and short nasal columella with a wide and depressed nasal tip, skeletal conditions, such as cleft palate, spinal column abnormalities, brachydactyly, brachymesophalangia, clinodactyly, and craniofacial anomalies, dermatoglyphic anomalies, mild-to-moderate intellectual disability, and postnatal growth deficiency.^{2,3} In some cases, urogenital and cardiac abnormalities, visual deficiencies, conductive, sensorineural or mixed hearing loss due to recurrent otitis media in infancy, and endocrine disorders including precocious puberty, diabetes insipidus, thyroid dysfunction, and obesity may occur.³ Several cases with the characteristics described above have been reported in the literature (Table 1).

The genetic mutations associated with KS are mainly found in the *KMT2D* and *KDM6A* genes.^{4,5} *KMT2D* (also called *MLL2* or *MLL4*) is located on the long arm of chromosome 12 (12q13.12). It encodes the histone-lysine methyltransferase 2D protein responsible for di- and tri-methylation of H3K4 in the enhancers and promoters necessary for transcriptional activation.^{6,7} This enzyme contains 5262 amino acid residues, 1 catalytic SET domain, 5 PHD domains, 2 ePHD domains, 1 HMG-I binding motif, and FY-rich motifs.^{8,9} Alterations in *KMT2D* are the leading cause of KS type 1.⁷ *KDM6A* (formerly known as *UTX*) is associated with KS type 2 and encodes a demethylase that eliminates the trimethylation of histone 3 lysine 27 and interacts with *KMT2D* in the regulation of gene expression.^{10,11} KS has variable expression, is inherited in an autosomal dominant fashion, and is associated with de novo mutations in most cases.^{1,12}

More than 650 genetic variants associated with KS have been identified. These include nonsense and missense mutations, indels, duplications, frameshifts and splice site variants. Most lead to truncated protein synthesis.^{12–14} Several cases of splicing variants linked with this syndrome have been reported (Table 2), and here we describe the case of

a patient with clinical characteristics compatible with KS and an intronic variant in *KMT2D* that explains her phenotype.

Case Presentation

An 11-year-old Colombian girl was delivered at 38 weeks of pregnancy without complication. Her mother and father were non-consanguineous and aged 32 years and 44 years, respectively, at the time of birth. Birth weight was 2625 g (3rd–10th percentile), and height was 49 cm (50th and 75th percentile). No facial or phenotypic abnormalities were noticed at birth. However, at the age of 16 months and at 3 years, she underwent a pupilloplasty due to the reparation of the coloboma. Her family history was unremarkable.

At age 8 years, she underwent surgical correction of her right eyelid. One year later, ophthalmologic examination showed microphthalmia in the right eye with an irregular pupil, inferonasal coloboma, iridectomized iris, and soft-tissue protrusion at the superolateral pouch with dermoid fat herniation. The left eye had an irregular pupil with iris atrophy. Audiometric examination showed mild-to-moderate sensorineural hearing loss in the right ear (PTA 44dB); and normal hearing in the left (PTA 10dB). Estimated radiographic bone age was 6 years. Cardiac echocardiography showed normal ejection fraction (76%). Renal ultrasonography showed ectasia of the left renal sinus. Renal scintigraphy revealed bilateral postinfectious scarring with preserved parenchymal function, a dilated left renal sinus, renal sinus ectasia with interruption, and a probable duplex calyx system; renal function was 56% in the right kidney and 44% in the left. Spinal radiography showed a lumbar curvature to the right with slightly increased lumbar lordosis.

At age 11 years, the Intelligence Quotient (IQ) assessment Wechsler Intelligence Scale for Children IV (WISC-IV) was performed with a total intelligence quotient testing score of 67; verbal comprehension score was 81 (average), perceptual reasoning score was 75 (low), working memory score was 68 (deficient), and information processing speed score was 62 (deficient). Height was 133 cm (4th percentile), weight was 40 kg (66th percentile), and head circumference was 52 cm (22nd percentile). Physical examination showed bilateral iris coloboma, right microphthalmia, inverse epicanthus, elongated palpebral fissures that inclined upwards, eversion of the lateral portion of the lower eyelid, anteverted nostrils, short columella, long philtrum, and normal ear position (Figure 1A and B). Acanthosis nigricans was observed in the neck and armpits, and she had overdeveloped breast

Figure 1 Facial characteristics. **(A)** Image of the patient where microphthalmia and eversion of the lateral third of the eyelid are observed. **(B)** Image of the patient with arched eyebrows, long palpebral fissures and wide nasal bridge, facial characteristics of kabuki syndrome. **(C)** Patient's whole face image shows the dysmorphic characteristics previously described.

tissue. Cardiopulmonary auscultation was normal. Her abdomen had an enlarged panniculus adiposus and was soft and depressible without mass or organomegaly. Extremity examination showed persistent digital pads and a Beighton score of 4/6. Neurologically, she was alert and cooperative.

Massive Parallel Sequencing of the Multigen Panel for KS was performed to evaluate *KMT2D*, *KDM6A*, *RAP1A*, and *RAP1B*. The mean vertical coverage was 325.14X, and the horizontal coverage was 99.46% (coding and splicing regions). This genetic panel detected an intronic *KMT2D* variant (*KMT2D* NM_003482.3:c.511–2A>T) in a heterozygous state. This variant was located in the fourth intron's acceptor site, which would produce an alteration in the splice between the fourth and fifth exon. Sanger sequencing using an ABI 3500 sequencer (Applied Biosystems, Thermo Fisher Scientific, Waltham, MA, USA) was then performed and confirmed the results. This variant has not been annotated in databases, such as Clinvar, ExAC, 1000 genomes and HGMD. Furthermore, it presents a DANN score of 0.9917 and it is classified as a probably pathogenic variant according to the recommendations of the American College of Medical Genetics and Genomics (ACMG) due to experimental data being required to confirm the pathogenicity of the variant. Besides, a segregation study was performed and showed a negative result in the parents, demonstrating that the patient's variant was de novo (Figure 2).

Discussion

KS is diagnosed clinically by the presence of facial, skeletal, and dermatoglyphic abnormalities, growth deficiency, and mild-to-moderate intellectual disability. The central genes etiologically associated with this condition are *KMT2D* and *KDM6A*, which are involved in epigenetic regulation.¹⁵

The patient in this case report had developmental delay and intellectual disability and exhibited a probably pathogenic *KMT2D* splice site variant (NM_003482.3: c.511–2A> T). This type of variant can produce various effects such as exon skipping, intron retention, transcribed non-coding sequences or non-transcribed coding sequences, resulting in partially or completely non-functional proteins.¹⁶ Therefore, according to the diagnostic criteria established by an international group of experts in 2018, it met the criteria for a definitive diagnosis of KS. Typical dysmorphic features, such as elongated palpebral fissures, arched eyebrows, a short columella with a sunken nasal tip (Figure 1A and B), and persistent finger pads, were also evident.⁴

In addition to the typical KS features, the patient presented with coloboma (Figure 1A), a less commonly reported feature (Table 1). However, the incidence of coloboma is considerably higher in KS patients (3.2%) than in the general population (0.011%).^{17,18} Coloboma can affect the iris, choroid, retina, and/or optic nerve.^{18,19} Hearing loss is also frequent in KS patients, but sensorineural hearing loss is rare.^{20,21} Some studies have reported dysplastic cochlea, enlarged vestibules, and

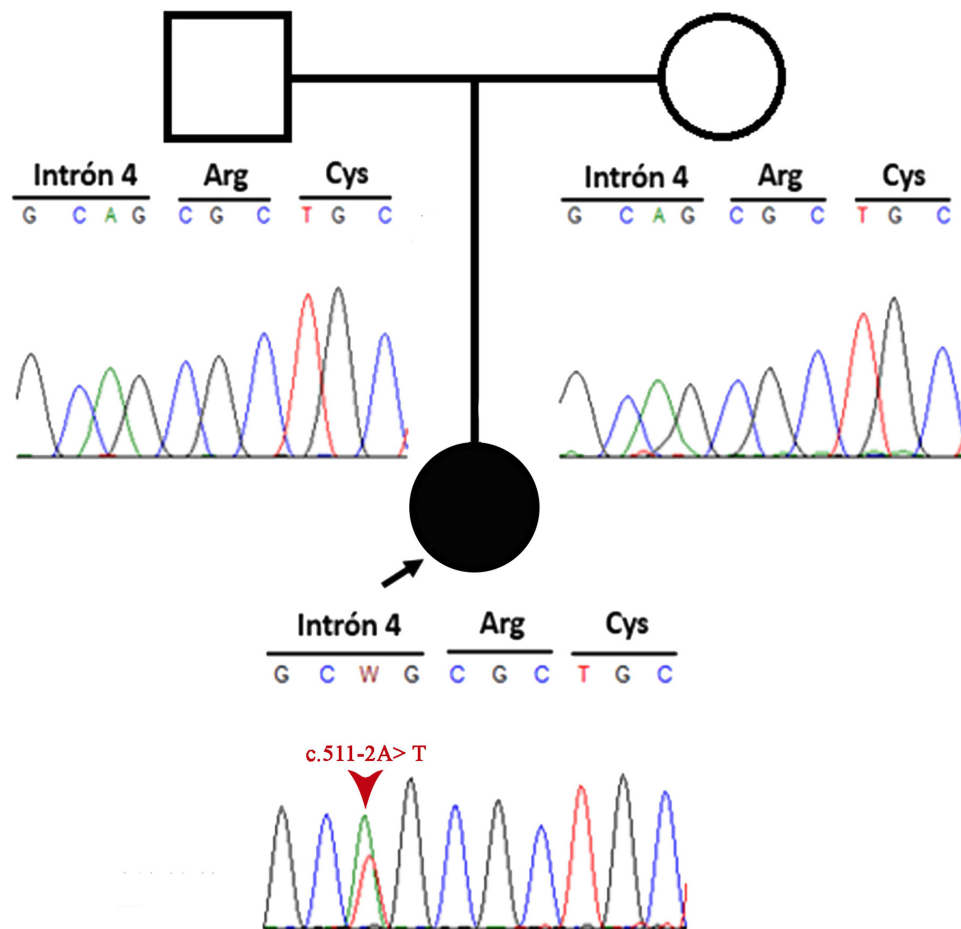

Figure 2 Pedigree information of the patient and Sanger sequencing electropherogram of both patient and her parents. The image shows a de novo mutation.

even absence of the cochlea and semicircular canals in KS patients, demonstrating that a wide variety of abnormalities at the ear level can occur.^{20,21} These findings can be explained by *KMT2D* disease-causing variant effects on histone trimethylation, which is required for the open chromatin conformation needed for gene expression, especially in the control of genes essential for embryonic development, including *HOX* genes.^{22,23} The splice score was calculated by Human Splicing Finder HSF algorithm and the variation c.522-2A>T was -35.16%. This finding indicates that the *KMT2D* variant results in alteration of the wild-type acceptor site and might affect the splicing process. The *KMT2D* variant in our patient was located at the acceptor site of the fourth intron. Bioinformatic analysis (HSF v 3.1) predicted splice alteration that leads to a modified splicing process between the fourth and fifth exons. The fifth exon encodes for a zinc finger plant homeodomain (PHD) that consists of 2 β sheets and 2 structure-stabilizing zinc atoms anchored by the Cys4-His-Cys3 motif.²³ This homeodomain recognizes the methylation state of N-terminal lysine residues in histone H3, whether H3K4 di-

tri-, or non-methylated, thus acting as a histone reader.^{24,25} This interaction allows the recognition and retention of the entire protein complex (in this case, *KMT2D*) at a specific site in the chromatin and contributes to the regulation of enzymatic activity in response to modifications present in histones.²⁶ Therefore, the variation c.522-2A>T can result in skipping the succeeding exon or the use of a cryptic splicing site, within exon 5, or downstream of the wild-type splice-acceptor site (Figure 3). However, experimental data are required to confirm this hypothesis. Anyhow, this intronic variant would lead to the altered synthesis of one of the PHD domains, which plays an essential role in selection of the histone-lysine methyltransferase 2D enzyme-binding site.

Conclusion

We report a new intronic *KMT2D* variant as a probable cause of KS. Most characteristics described in our patient are similar to those previously reported. However, our patient also exhibited coloboma and sensorineural hearing loss, which are less common.

Figure 3 Alteration of splicing mechanism. **(A)** Schematic of the *KMT2D* genomic locus and variant c.511-2A>T. **(B)** Shows the splicing alteration, which represent a missplicing of *KMT2D* by mutation at the intron 4 resulting in the activation of alternative splice sites (green pin). **(C)** Shows the alteration of mRNA. The activation of cryptic splicing site in exon 5 results in an incomplete inclusion of this exon in the mRNA. Recognition of wild-type acceptor site of exon 6 results in a complete exclusion of exon 5 in the mRNA.

Data Sharing Statement

The datasets used and/or analyzed during the current study are available from the corresponding author on reasonable request.

Ethics Approval and Informed Consent

This study was approved by the Ethics Committee of Fundacion Valle del Lili, Colombia (human study protocol #1504) and performed in accordance with the ethical standards found in the Declaration of Helsinki. Written informed consent was obtained from the parents of the subjects. Information revealing the subject's identity was not included in the manuscript. The patient was identified by number and not by her real name.

Consent for Publication

Institutional approval was required to publish the case details. All the images and patient material presented in this study have been consented for publication and they are available to see upon request.

Acknowledgments

We thank the patient and her parents for agreeing to the pub HSF: Human Splicing Finder publication of this report. We also thank the people who have contributed to the development and execution of this study.

Author Contributions

All authors contributed to data analysis, drafting or revising the article, have agreed on the journal to which the article will be submitted, gave final approval of the version to be published, and agree to be accountable for all aspects of the work.

Funding

All forms of support and funding for study design, data collection, data analysis and manuscript writing were provided by the employers of the authors (Universidad Icesi and Fundación Valle del Lili).

Disclosure

The authors have no conflicts of interest to declare.

The Application of Clinical Genetics

Dovepress

Publish your work in this journal

The Application of Clinical Genetics is an international, peer-reviewed open access journal that welcomes laboratory and clinical findings in the field of human genetics. Specific topics include: Population genetics; Functional genetics; Natural history of genetic disease; Management of genetic disease; Mechanisms of genetic disease;

Counselling and ethical issues; Animal models; Pharmacogenetics; Prenatal diagnosis; Dismorphology. The manuscript management system is completely online and includes a very quick and fair peer-review system, which is all easy to use. Visit <http://www.dovepress.com/testimonials.php> to read real quotes from published authors.

Submit your manuscript here: <https://www.dovepress.com/the-application-of-clinical-genetics-journal>
