Abstract: Pyridine-based ring systems are one of the most extensively used heterocycles in the field of drug design, primarily due to their profound effect on pharmacological activity, which has led to the discovery of numerous broad-spectrum therapeutic agents. In the US FDA database, there are 95 approved pharmaceuticals that stem from pyridine or dihydropyridine, including isoniazid and ethionamide (tuberculosis), delavirdine (HIV/AIDS), abiraterone acetate (prostate cancer), tacrine (Alzheimer's), ciclopirox (ringworm and athlete's foot), crizotinib (cancer), nifedipine (Raynaud's syndrome and premature birth), piroxicam (NSAID for arthritis), nilvadipine (hypertension), roflumilast (COPD), pyridostigmine (myasthenia gravis), and many more. Their remarkable therapeutic applications have encouraged researchers to prepare a larger number of biologically active compounds decorated with pyridine or dihydropyridine, expandeing the scope of finding a cure for other ailments. It is thus anticipated that myriad new pharmaceuticals containing the two heterocycles will be available in the forthcoming decade. This review examines the prospects of highly potent bioactive molecules to emphasize the advantages of using pyridine and dihydropyridine in drug design. We cover the most recent developments from 2010 to date, highlighting the ever-expanding role of both scaffolds in the field of medicinal chemistry and drug development.

<span id="page-0-4"></span>**Keywords:** nitrogen heterocycles, pharmaceuticals, bioactive compounds, current trend, substituent effect

## **Introduction**

<span id="page-0-9"></span><span id="page-0-8"></span><span id="page-0-7"></span>Heterocycles are intricately woven into basic processes of life and play a crucial role in the pharmaceutical and agrochemical industries.<sup>1</sup> In terms of pharmacological, physicochemical, pharmacokinetic, and toxicological properties, heterocyclic structures are found in  $>90\%$  of newly synthesized and marketed drugs.<sup>2</sup> Medicinal chemistry has evolved from an empirical practice involving the synthesis of novel substances and then gauging their biological activity.<sup>3</sup> A plethora of synthetic compounds with heterocyclic structural frameworks have been identified — with privileged six-membered N-containing pyridine and dihydropyridine rings linked to a diverse range of bioactivity.<sup> $4-7$ </sup> In the realm of six-membered heterocyclic structures, they have unique and interesting characteristics. Owing to their therapeutic potential, medicinal chemists have recently become drawn toward scaffolds in order to synthesize a wide range of novel bioactive molecules.<sup>[8](#page-42-4)</sup>

<span id="page-0-13"></span><span id="page-0-12"></span><span id="page-0-11"></span><span id="page-0-10"></span>In pharmaceutical targets, pyridine and its precursor molecule dihydropyridine are among the most prevalent structural units.<sup>[9](#page-42-5)[,10](#page-42-6)</sup> In plants, they are mostly found in the alkaloids. $11$  In biological systems, redox reactions of nicotinamide adenine dinucleotide

<span id="page-1-1"></span>(NAD) reduces its pyridine ring into dihydropyridine, rendering NADH. Similar redox reactions are also present in anabolic reactions involving NAD phosphate (NADP<sup>+</sup>/NADPH) interconversion.<sup>12</sup> A glance at the US Food and Drug Administration (FDA) database reveals that pyridine- and dihydropyridine-containing drugs constitute nearly 14% and 4% of *N*-heterocyclic drugs approved by the agency [\(Figure 1](#page-1-0)). For these 18% of drugs, the major therapeutic areas of focus are infectious diseases, inflammation, the nervous system, and oncology.

Substitution-type analysis of pyridine-containing drugs revealed that the ring is mostly monosubstituted (60%) in the database, whereas di-, tri-, and tetrasubstitution represented 22%, 12%, and 6%, respectively [\(Figure 2A](#page-2-0)). For dihydropyridine-containing drugs, neither mono- nor disubstitution was observed for the *N*-heterocyclic ring. However, trisubstitution of the dihydropyridine ring was the most abundant substitution type for this class of drugs. Tetra-, penta-, and hexasubstitution on the *N*-heterocyclic ring were 11%, 21%, and 5%, respectively ([Figure 2B](#page-2-0)).

In recent years, synthetic chemists have been focusing on developing new analogues that employ pyridine or dihydropyridine templates in their molecular design, in order to study their mechanisms of action to discover new pharmaceutical leads. The importance of the two heterocycles in medicinal chemistry and chemical sciences can be seen by the sheer number of publications appearing between 2010 and 2020 [\(Figure 3](#page-2-1)).

<span id="page-1-4"></span><span id="page-1-3"></span><span id="page-1-2"></span>Most reviews on this topic have concerned synthetic strategies to prepare pyridine- or dihydropyridine-containing compounds[.2,](#page-42-1)[10](#page-42-6)[,13–16](#page-42-9) For either of the two scaffolds, one can also find many reviews delineating their therapeutic potential concerning a specific malady.<sup>[17–28](#page-42-10)</sup> Most reviews on pyridinecontaining compounds have examined only their anticancer potential.<sup>21[,22](#page-42-12)</sup> Likewise, several reviews on dihydropyridinecontaining compounds typically scrutinized their calcium

<span id="page-1-0"></span>

<span id="page-2-6"></span><span id="page-2-5"></span><span id="page-2-4"></span><span id="page-2-3"></span><span id="page-2-2"></span>channel–blocking abilities for the treatment of hypertension and associated ailments. $19,24,26-28$  $19,24,26-28$  $19,24,26-28$  The neuroprotective ability of dihydropyridine derivatives has also been examined.<sup>23</sup> Lapidot et al summarized the antibacterial activity of dihydropyridine-containing peptidomimetics.<sup>25</sup> For substituted 1,4dihydropyridine, medicinal versatility and anticipable therapeutic effects have been the focus of past reviews,  $29-31$  eg, Khedkar et al briefly discussed the pharmacological importance of this type of molecule. $30$  To the best of our knowledge, a review focusing on the therapeutic potential of pyridine- and

dihydropyridine-containing compounds has never been published. Herein, we present commercially available drugs while discussing the major therapeutic potential of synthetic bioactive molecules with either of the two scaffolds. The review covers a sizable period in the scientific literature, including the publications from 2010 to date, thereby providing a broad picture of approved drugs and bioactivity reported for pyridineor dihydropyridine-containing compounds, and is valuable material for those interested in exploring this class of compounds for further medicinal and clinical applications.

# **Pyridine and Dihydropyridine Scaffolds in Natural Products and Commercially Available Drugs**

Pyridine and dihydropyridine generate a suite of versatility when it comes to creating libraries of compounds with different functional groups for screening against different biological targets. Many natural products contain pyridinebased rings ([Figure 4](#page-4-0)), including the vitamins (niacin and vitamin  $B_6$ ), coenzymes (NAD, NADP), alkaloids (trigonelline, [–]-oxirene, [+]-anabasine, huperzine A, paecilomide, cystine), antibiotics (nikkomycin, collismycin), and many more compounds.<sup>[11](#page-42-7)</sup>

<span id="page-3-2"></span><span id="page-3-0"></span>In pharmaceuticals, nitrogen-containing heterocycles are considered instrumental structural constituents.<sup>32</sup> The presence of pyridine or dihydropyridine ring systems can have a substantial impact on pharmacological profiles of drugs and bioactive molecules.<sup>33</sup> For example, a pyridine motif in a drug improves its biochemical potency and metabolic stability, enhances permeability, and fixes protein-binding issues.<sup>33</sup> Some interesting examples of the pyridine effect are highlighted in [Figure 5:](#page-5-0) Vanotti et al were able to develop the potent Cdc7 kinase inhibitor **2** by substituting the phenyl group of 1 with pyridine.<sup>34</sup> Similarly, metabolic stability of thiourea-based nicotinamide phosphoribosyltransferase inhibitor **3** is improved 160-fold when its terminal phenyl ring is replaced with pyridine in **4**. [35](#page-43-2) A heterocyclic pyridine ring in a molecule is also capable of enhancing its cellular permeability. For example, Doller et al identified a pyridine-containing positive allosteric modulator **6** with 190-fold the cellular permeability of **5**. [36](#page-43-3) For the treatment of schizophrenia, proteinbinding issues of positive allosteric modulator **7** were resolved by the introduction of an additional pyridine ring in **8**. [37](#page-43-4) It is thus pertinent to say that substitution of nitrogen-containing heterocyclic rings profoundly affects the physicochemical properties of the bioactive molecule.<sup>[33](#page-43-0)</sup>

<span id="page-3-13"></span><span id="page-3-12"></span><span id="page-3-11"></span><span id="page-3-10"></span><span id="page-3-9"></span><span id="page-3-8"></span><span id="page-3-7"></span><span id="page-3-6"></span><span id="page-3-5"></span><span id="page-3-4"></span><span id="page-3-3"></span><span id="page-3-1"></span>There is a plethora of commercially available drugs in the market which contain pyridine rings, such as abiraterone for prostate cancer,  $38$  enpiroline for malaria,  $39$  nicotinamide for pellagra, $40$  nikethamide as a respiratory stimulant, $41$  piroxicam for arthritis, $42$  isoniazid for tuberculosis, $43$  pyridostigmine for myasthenia gravis,<sup>44</sup> tropicamide as an antimuscarinic,  $45$  doxylamine for allergies,  $46$  omeprazole for ulcers,  $47$  delavirdine as an antiviral against HIV/ AIDS,<sup>48</sup> enisamium iodide for influenza,<sup>49</sup> and tacrine as an inhibitor of the AChE enzyme<sup>50</sup> for Alzheimer's disease prevention ([Figure 6\)](#page-6-0).

<span id="page-3-16"></span><span id="page-3-15"></span><span id="page-3-14"></span>Dihydropyridine ring–containing drugs mostly act as calcium-channel blockers, $51$  and are frequently employed for the treatment of hypertension and heart-related problems[.52](#page-43-19) Such drugs include nilvadipine, nifedipine, amlodipine, azelnidipine, clevidipine, felodipine, and pranidipine. Some of these drugs are also used to cure many other therapeutic conditions[.53](#page-43-20) For example, nifedipine is being used for Raynaud's syndrome and premature birth.<sup>[54](#page-43-21)</sup> Dihydropyridine-containing huperzine, a natural product, acts as an AChE inhibitor and is employed in the treatment of Alzheimer's disease, whereas ciclopirox is widely used as an antifungal agent to cure ringworm and athlete's foot disease [\(Figure 7\)](#page-7-0).

<span id="page-3-18"></span><span id="page-3-17"></span>Milrinone and amrinone are the two commercially avail-able vasodilators,<sup>[55](#page-43-22)</sup> and contain both pyridine and dihydropyridine ring systems in their structures [\(Figure 8\)](#page-7-1). In general, pyridine- and dihydropyridine-containing drugs are mostly used as antimicrobial, antiviral, anticancer, antioxidant, antihypertensive, antidiabetic, antimalarial, and antiinflammatory agents, psychopharmacological antagonists, and antiamebic agents.<sup>56–62</sup> A comprehensive list of commercially available drugs containing pyridine and/or dihydropyridine scaffolds and their mechanism of action is summarized in [Table 1.](#page-8-0)

<span id="page-3-19"></span>Analysis of the substitution pattern in FDA-approved drugs has revealed that the 1,4-dihydropyridine ring in the drugs was mostly substituted at the *para*-position (4). Disubstitution at both *ortho*-positions (2 and 6) were observed in eleven drugs, while one drug had monosubstitution at the *ortho*-position (2). Similarly, three drugs had monosubstitution at the *meta*-position (3), whereas ten drugs had disubstitution at *meta*-positions (3 and 5) of the 1,4-dihydropyridine ring. For brevity, the substitution patterns of pyridine and dihydropyridine ring systems in FDAapproved drugs are illustrated in [Figure 9.](#page-15-0)

# **Pharmacological Activity**

On the therapeutic front, pyridine- and dihydropyridine-containing compounds possess versatile bioactivity, due to which they are the integral in numerous drugs. The literature revealed many examples wherein this class of compounds demonstrated promising pharmacological properties.

# Cardiovascular Drugs and Bioactive **Compounds**

Hypertension is among the main risk factors of cardiovascular disease. Many different types of antihypertensive

<span id="page-4-0"></span>

Figure 4 Pyridine and dihydropyridine ring system in medicinally important natural products.

drugs are employed to treat the problem. Main classes of such drugs include  $α$ - and  $β$ -adrenergic inhibitors, renin inhibitors, vasodilators, diuretics, calcium-channel blockers, angiotensin converting–enzyme inhibitors, and many more ([Figure 10\)](#page-16-0). Pyridine-containing torsemide is an

FDA-approved drug that promotes diuresis, thereby lowering the blood pressure of the patient. Pyridine- and dihydropyridine-containing amrinone and milrinone are beta-adrenergic blockers, also called β-blockers, to help manage hypertension via vasodilation and ultimately save

<span id="page-5-0"></span>

**Figure 5** Effect of pyridine on key pharmacological parameters.

the patient from a second heart attack. Disruption of calcium movement through cellular channels is another strategy to lower blood pressure. Most of the calcium antagonists in the FDA database contain dihydropyridine scaffolds, with penta-substitution pattern observed for the ring ([Figure 11\)](#page-17-0).

In 2014, *N*-propargyl–substituted derivatives of 1,4- DHP derivatives were synthesized by Rucins et al, who incorporated pharmacophore moieties into their structures and investigated their calcium channel–blocking activity. In SH-SY5Y–type neuroblastoma cells (which contain  $Ca^{2+}$ channels of L-and N-type) and A7r5 cells (which are rat aortic muscle cells expressing L-type  $Ca^{2+}$  channels), and impact of newly synthesized compounds on intracellular concentration of calcium  $[Ca^{2+}]$  was studied. Among the series, compounds **9** and **10** with *n*-dodecyl pyridinium moiety as an amphiphilic group exhibited the strongest calcium antagonistic activity in SH-SY5Y neuroblastoma cells (IC<sub>50</sub> = 5–14 mM), and A7r5 type lines (IC<sub>50</sub> = 0.6–0.7 mM). These compounds demonstrated moderately effective antioxidant activity. Compound **10** had no effect on mitochondrial function at dosages comparable to that used to block L-type calcium channels, and no damage was seen in

**https://doi.org/10.2147/DDDT.S329547** 

vivo. As a consequence, this compound can be regarded as safe up to 100 mg/kg, with no toxicity. It was observed that the 1,4-DHP ring–bearing propargyl group at position 1 did not significantly influence the bioactivity of the tested derivatives. Therefore, compounds with *n*-dodecyl pyridinium moiety at the *para*-position [\(Figure 11\)](#page-17-0) might be the lead molecules for subsequent modifications and in vivo studies of cardiovascular and neurological disorders.[176](#page-47-0)

<span id="page-5-3"></span><span id="page-5-2"></span><span id="page-5-1"></span>Nitrendipine **11** is a DHP-type calcium antagonist with a simple structure, but low potency. Antihypertensive actions of nitrendipine analogues can be improved by increasing the alkyl-chain length at the 3 or 5 position.<sup>177,178</sup> Zhou et al synthesized nitrendipine analogues, and their antihypertensive properties were assessed in spontaneously hypertensive rats by means of intravenous immunoglobulin administration. *S*- and *R*-enantiomers had different calcium antagonistic activity in various studies[.179](#page-47-3) It was found that the*S*-enantiomer had 100-fold the antihypertensive properties of the *R*-enantiomer [\(Figure 12\)](#page-17-1). Moreover, the efficacy of nitrendipine analogues was further enhanced by elongating carbon chain-length. These findings suggest that alkyl-chain length at position 5 is closely linked to the antihypertensive effects of nitrendipine analogues. DHP's antihypertensive effects

<span id="page-6-0"></span>

Figure 6 Some commercially available drugs containing the pyridine scaffold.

<span id="page-6-1"></span>were attenuated by extra-long or extra-short alkyl chains at position 5. On position 5 of DHP, an alkyl chain containing seven carbon atoms is the most appropriate length. Therefore, the strongest antihypertensive effect was observed for 5-*n*-heptyl-3-methyl-2,6-dimethyl-4-(3-nitrophenyl)-1,4 dihydropyridine-3,5-dicarboxylate [(±)-**12**]. Antihypert ensive effects of  $(\pm)$ -12 and  $+$ -12 were compared, with  $+$ -isomer being 1.79 times more potent at a dosage of 2 mg/kg than the raceme.<sup>180</sup>

Calcium channel–antagonistic activity of phenyl amino imidazolyl–bearing 1,4-dihydropyridines were also investigated by Zarghi et al. His research group replaced the *ortho*-nitrophenyl group at the *para*-position of nifedipine with a 2-methylthio-1-phenylamino-5-imidazolyl substituent. Then, calcium channel–antagonist activity  $(IC_{50})$  were determined in guinea pigs, which revealed that the contractile responses elicited by these novel dihydropyridinecontaining compounds inhibited higher  $K^+$  concentrations

<span id="page-7-0"></span>

<span id="page-7-1"></span>**Figure 8** FDA-approved vasodilators containing both pyridine and dihydropyridine scaffolds.

in a dose-dependent manner. In the muscular membrane, these effects were comparable to those shown by nifedipine and might be attributed to the suppression of  $Ca^{2+}$ entry via voltage-dependent calcium channels. However, it should be noted that the gut features a complex network of tissue, and we cannot rule out the potential of these compounds acting differently on distinct muscular and neuronal sites. A comparison of the activity of alkyl ester series in these compounds shows that by increasing the chain length of methylene at  $C_3$  and  $C_5$  ester substituents, activity reduces. For example, the *t*-butyl ester–containing compound was the least active among the series. Overall results suggested that most of the compounds had activity comparable to those of nifedipine, with the exception of two compounds, **13** and **14**, being more active than nifedipine ([Figure 13\)](#page-17-2). As such, they can be potential leads for the design of calcium-channel blockers.<sup>[181](#page-47-5)</sup>

<span id="page-7-3"></span><span id="page-7-2"></span>Kumar et al reported anticoagulant activity for dihydropyridine-containing compounds, which was assessed using activated partial thromboplastin time and prothrombin time coagulation assays. Compound **15** [\(Figure 14](#page-18-0)) had a coagulation time of 720.35 seconds at 30 mg/mL. The standard drug heparin was used at s similar concentration.[182](#page-47-6)

<span id="page-8-16"></span><span id="page-8-15"></span><span id="page-8-14"></span><span id="page-8-13"></span><span id="page-8-12"></span><span id="page-8-11"></span><span id="page-8-10"></span><span id="page-8-9"></span><span id="page-8-8"></span><span id="page-8-7"></span><span id="page-8-6"></span><span id="page-8-5"></span><span id="page-8-4"></span><span id="page-8-3"></span><span id="page-8-2"></span><span id="page-8-1"></span><span id="page-8-0"></span>

<span id="page-14-8"></span><span id="page-14-7"></span><span id="page-14-6"></span><span id="page-14-5"></span>Dyslipidemia is a complex disease that promotes ather-osclerosis and cardiovascular problems.<sup>[183](#page-47-7)</sup> In 2001, the pyridine-containing drug cerivastatin was withdrawn from the market due to rhabdomyolysis risk. Later, another drug in the statin class, pitavastatin, was developed for lowering blood cholesterol [\(Figure 15\)](#page-18-1).

In 2016, antihyperlipidemic compounds of type (benzoylphenyl)pyridine-3-carboxamide were reported [\(Figure 16](#page-18-2)), and **16**–**17** demonstrated excellent in vivo activity.[184](#page-47-8) The antidyslipidemic activity of the compounds were tested in vivo.

<span id="page-14-9"></span>These compounds were able to lower total cholesterol (TC) from 11.0% to 24.8%. The compounds showed plasma phospholipid–lowering (PL) activity ranging from 5.7% to 28.5%. The most active compound in the series was **17** (−28.5%), whereas gemfibrozil (39.1% PLdecreasing activity) was the least active. The scavenging capability of compounds was also tested against the production of superoxide ions  $(O^{2-})$  using 100 and 200 mg/ mL allopurinol. Antioxidant activity of the compounds in the series was substantial, and those with *tert*-butyl ester functionality were found to be the most active. Compounds **18**–**22** demonstrated potential antidyslipidemic potential, but compounds **21**–**22** exhibited considerable antioxidant activity [\(Figure 17\)](#page-19-0). It can tentatively be assumed that the ester group plays a key role in differentiating antidyslipidemic and antioxidant activity. Antidyslipidemic potential was shown by those compounds that contained methyl/ethyl ester groups, whereas antioxidant activity was displayed by compounds with *tert*-butyl ester functionality.<sup>[185](#page-47-9)</sup>

<span id="page-14-10"></span>Although many dihydropyridine-containing drugs are commercially available to manage hypertension, we, believe that further research in the pyridine–dihydropyridine class of compounds will lead to the discovery of new pharmaceuticals to handle complications associated with cardiovascular diseases.

# Anti-Infectious Drugs and Bioactive Compounds

#### Antibacterial Agents

Antibiotic resistance is a serious threat to public health, driving the search for novel inhibitors of bacteria. Most antibiotics are being resisted by bacterial pathogens, rendering the development of novel, more effective antibacterial drug candidates a critical requirement. In the last 10 years, the FDA has approved many pyridine-containing

<span id="page-15-0"></span>

Figure 9 Substitution-pattern analysis in pyridine and dihydropyridine in FDA-approved drugs.

antibiotics, such as ceftaroline fosamil, tedizolid, ceftazidime, and delafloxacin [\(Figure 18](#page-19-1)).

Jo et al synthesized oxazolidinone-bearing pyridine derivatives, which had potent antibacterial activity. In vitro and in vivo antibacterial studies were performed against troublesome Gram-negative and Gram-positive strains of bacteria and two antibiotic-resistant strains. Several substituted (hetero)aromatic rings were tolerated on the pyridine moiety, and the presence or orientation of the methyl group in the (hetero)aromatic rings had a profound effect on antibacterial activity. The most active derivatives, **23**–**25** ([Figure 19](#page-20-0)), displayed potent activity against a wide range of drug-resistant bacteria, as well as *Moraxella catarrhalis* and *Haemophilus influenzae*, and had longer half-lives in vivo than linezolid. They had 4–16 fold the in vitro activity of linezolid, and and double the in vivo efficacy.<sup>186</sup>

<span id="page-15-1"></span>In another study, oxazolo[4,5-*b*]pyridine derivatives were synthesized to derive antimicrobial agents. These compounds had excellent activity against methicillin-resistant *Staphylococcus aureus*, which is responsible for widespread hospital-acquired infections. Compounds **28** and **31**  were the most potent, with MIC values of 1.56–25 µg/mL, while **26, 27, 29, 30, 32**, and **33** showed moderate activity  $(6.25-50 \mu g/mL)$  in comparison to the conventional drugs streptomycin and ampicillin [\(Figure 20\)](#page-20-1). Further studies revealed that oxazolo[4,5-*b*]pyridine analogues were more active against Gram-positive bacteria than Gram-negative bacteria. Compounds **28** and **31** had potent activity against *S. aureus* methicillin-resistant strains, with activity of 1.56–3.12 µg/mL, while standard drugs (ampicillin and streptomycin) had MIC values of 6.25–12.5 µg/mL. These compounds were also found to be active against other bacterial strains. Furthermore, the synthesized compounds were docked in the enterotoxin protein of *S. aureus*, which is a type A staphylococcal enterotoxin. Significant antibacterial activity for **28** and **31** in comparison to the standard drugs ampicillin and streptomycin was further validated by in vitro and in silico studies. The compounds were then tested for ligand–protein binding (MRSA protein) affiniy toward *S. aureus*, wherein the compounds had higher ligand–protein binding affinity than the stand drugs. $187$ 

<span id="page-15-2"></span>Novel pyrazolo[3,4-*b*]pyridine derivatives of 4-thiazolidinone Schiff bases, and azetidin-2-ones have also been synthesized and screened for antimicrobial activity.<sup>188</sup> Most compounds exhibited moderate–high activity at 0.12–62.5 µg/mL, wherein amphotericin B, ampicillin, and gentamicin were used as standard antimicrobial agents. Against the *Fusarium oxysporum* fungal strain, compound **37** had an MIC of 0.98 µg/mL, comparable to that of the standard antimicrobial drug amphotericin B. Significant cytotoxic activity was observed for these compounds against the HepG2 cell line, with  $IC_{50}$  of 0.0158– 71.3  $\mu$ M in comparison to doxorubicin (IC<sub>50</sub> = 0.008  $\mu$ M). Compounds  $34-38$  also had antiproliferative activity (IC<sub>50</sub>)  $= 0.0001 - 0.0211$   $\mu$ M) against the MCF7 cell line [\(Figure 21\)](#page-21-0). Specifically, highly significant antiproliferative efficacy was displayed by compound **37** against MCF7 cells and HepG2, with  $IC_{50}$  of 0.0001  $\mu$ M and 0.0158 µM, respectively. These results suggest that these compounds might lead toward the development of promising and novel antimicrobial and antiproliferative drug candidates. These compounds undoubtedly hold great potential in the quest to develop novel antiproliferative and antimicrobial agents.<sup>[188](#page-47-17)</sup>

<span id="page-15-3"></span>Dihydropyridines bearing thiazole derivatives were initially assessed with in silico molecular docking simulations to investigate their possible DNA gyrase inhibitory activity. Antibacterial activity was then assessed to validate the results of computational studies, wherein compound **39** demonstrated the highest efficacy against *Aspergillus flavus* and compound **40** had significant potency against *C. albicans* and *A. flavus* [\(Figure 22\)](#page-21-1).

<span id="page-16-0"></span>

<span id="page-18-2"></span>

**Figure 16** Antihyperlipidemic (benzoylphenyl)pyridine-3-carboxamide compounds.

*Pseudomonas aeruginosa*, *S. aureus*, *Staphylococcus epidermidis*, Escherichia coli, Bacillus cereus, and Gram-positive bacteria showed greater inhibitory activity than Gram-negative bacteria. Most of the synthesized compounds were highly potent against *S. aureus* and *S. epidermidis*. Compounds **41** and **42** had strong antibacterial effects with excellent MIC and selectivity-index values ([Figure 23\)](#page-21-2). The key point in this study was the single-step synthesis of oxadiazole-pyridine derivative. This approach with sufficient molecular modification could be adopted as a cost-effective strategy to produce potent antimicrobial agents.<sup>190</sup>

In another study, 1,3,4-oxadiazole derivatives containing indole and pyridine waere synthesized and evaluated against two strains of *Mycobacterium tuberculosis*  — H37Ra and BCG — both in dormant and active conditions. Compound **43**–**45** showed remarkable antitubercular activity ([Figure 24](#page-22-0)). Antiproliferative activity of the synthesized compounds weas also tested on HeLa, PANC1, and A549 cell lines using modified MTT assays. Most were acytotoxic. Based on MIC values and cytotoxicity results, the selectivity-index values determined for **43**–**45**, which were highly potent against *Mycobacterium bovis* BCG, while the compounds had index values  $\geq$ 10. In addition, molecular docking studies were performed at the active site of enoyl reductase (InhA) for compounds **43**–**45**. The encouraging results substantiated by selectivity, potency, and low cytotoxicity indicate these derivatives as potential antitubercular lead agents.<sup>[9](#page-42-5)</sup>

In the FDA database, one can find many pyridinecontaining drugs, such as isoniazid, ethionamide, and prothionamide, that are highly effective against mycobacteria for the treatment of tuberculosis ([Figure 25](#page-22-1)).

Further efforts to discover new bioactive compounds resulted in the synthesis of 2-(1-adamantylthio) pyridine

<span id="page-19-0"></span>

**Figure 20** Oxazolo[4,5-*b*]pyridines containing antibacterial agents with remarkable activity.

derivatives, which were screened for antibacterial activity against 27 strains, antimalarial activity against *Plasmodium falciparum*, and anticancer activity against HepG2, A549, HuCCA1, and MOLT3 cell lines. The results suggested that 2-(1-adamantylthio)pyridine–type compounds constituted a new class of antibacterial, antimalarial, and anticancer agent with potential therapeutic applications. All the compounds were highly active against streptococci, showing antigrowth activity of 15–30  $\mu$ g/mL. Compounds **46**–**49** were potent antimalarial, anticancer,

and antibacterial agents ([Figure 26](#page-22-2)). Surprisingly, 6-(1 adamantylthio)nicotinonitrile **49** had selective antimicrobial activity against β-hemolytic streptococcus, *Edwardsiella tarda*, *Vibrio parahaemolyticus*, and *Vibrio cholerae*. These findings suggest that compound **49** could be a promising antibacterial agent with potential ofor further improvement in its therapeutic properties.<sup>[191](#page-47-20)</sup>

<span id="page-20-2"></span>In summary, pyridine-containing compounds hold great promise for the development of pharmaceuticals against drug-resistant bacteria, since they exert

<span id="page-21-0"></span>

<span id="page-21-1"></span>**Figure 21** Pyrazolo[3,4-*b*] pyridine–bearing compounds with significant effect against various Gram-positive and Gram-negative bacterial strains.

<span id="page-22-2"></span>**Figure 25** Pyridine-containing drugs against mycobacteria.

**Figure 26** 2(1-adamantylthio) pyridine derivatives with potent antimicrobial activity.

<span id="page-22-7"></span><span id="page-22-6"></span><span id="page-22-5"></span><span id="page-22-4"></span><span id="page-22-3"></span>Pyridine-containing triazolo derivatives demonstrate remarkable antifungal properties. For example, thiadiazole-containing triazolopyridines have been found to display antifungal activity against *Pseudoperonospora cubensis*, *Pseudomonas syringae* pv. Lachrymans, and *Corynespora cassiicola*. [192](#page-47-21) In 2016, Mu et al reported a series of hydrazone-containing triazolopyridine derivatives with significant antifungal activity against *Stemphylium lycopersici*, *Botrytis cinerea*, and *F. oxysporum*. [193](#page-47-22) In 2019, Wei et al designed inulineSchiff bases bearing pyridine rings and evaluated their in vitro antifungal properties against *Phomopsis asparagi*, *F. oxysporum* f. sp. *niveum*, and *Botrytis cinerea*. [194](#page-47-23) Pyridinegrafted chitosan polymers have also been reported with improved antifungal properties.<sup>[195](#page-47-24)</sup> Pyridine has beeno grafted onto starch to control different fungi. $196$  In summary, fusing triazole and pyridine derivatives may lead to the

development of broad-spectrum antifungal agents against MDR fungal infections.

#### Antimalarial Agents

A series of novel pyridyl–indole hybrids were described by Heba et al, which were designed using a fragmentbased strategy. The compounds were tested for antimalarial activity against chloroquine-sensitive (D6) and chloroquine-resistant (W2) strains of *P. falciparum*. Compounds **50**–**55** ([Figure 27\)](#page-23-0) displayed the most potent antimalarial activity (IC<sub>50</sub> =1.47–9.23  $\mu$ M for D6 and IC<sub>50</sub> =1.16–7.66 μM for W2). Selectivity-index values were 1.47–8.3 for D6 and 1.7–10 for W2. Compounds **50**, **51**, and **54** demonstrated antimalarial activity against D6 and W2. The distinctive feature of these compounds was the absence of substitution at the C2 position of the pyridine ring.

<span id="page-23-0"></span>

Potent antimalarials against P. falciparum

**Figure 27** Highly active antimalarial pyridyl–indole hybrids.

<span id="page-23-1"></span>

# P. falciparum DXR  $Ki = 1.9$  nM P. falciparum killing  $EC_{50}$  = 170 nM

**Figure 28** Highly potent antimalarial pyridine-containing fosmidomycin derivative.

Furthermore, binding interactions of these compounds with quadruple mutant *P. falciparum* dihydrofolate reductase enzyme were investigated via molecular docking studies. Compounds **50**–**52** were the most active at the binding cavities of quadruple-mutant Pf DHFR-TS–active sites, indicating suitable binding associations that might be the mechanism influencing their activity as antimalarial agents[.197](#page-47-26)

<span id="page-23-2"></span>Xue et al reported fosmidomycin derivatives containing the pyridine scaffold that inhibited *P. falciparum* DXR

with  $K_i$  values of 1.9–13 nM. The most potent compound [\(Figure 28](#page-23-1)) was elevenfold as active as fosmidomycin.<sup>198</sup>

We believe that pyridine-based compounds have immense potential for the development of antimalarial drugs, since they exhibit antimalarial effects due to hydrogen-bond interactions between pyridine nitrogen and cysteine of target proteins in the pathogen, thereby rendering such compounds highly effective against chloroquineresistant strains.[198](#page-47-27)

#### <span id="page-23-3"></span>Antiviral Agents

For the treatment of HIV infection, the FDA data-base contains many pyridine- and dihydropyridine-containing drugs, such as nevirapine, tipranavir, doravirine, and indinavir ([Figure 29](#page-24-0)).

<span id="page-23-4"></span>In the last decade, research into new antiviral agents has resulted in the synthesis of pyridotriazines, furopyridines, and pyridothiadiazepinthiones.[199](#page-47-28) Among the synthesized ones, a few molecules had appreciable efficacy against adenovirus type7 and the rotavirus Wa strain. Compound **56**  suppressed viral titers by 60% and 53.3% for the rotavirus Wa strain and adenovirus type 7, respectively, and compound **57** demonstrated 50% and 53.3% reductions, respectively. These compounds [\(Figure 30](#page-24-1)) can potentially be used as therapies for rotavirus and adenovirus type 7, which currently have no adequate treatment options.<sup>[199](#page-47-28)</sup>

<span id="page-24-0"></span>

<span id="page-24-1"></span>**Figure 29** Pyridine/dihydropyridine-containing drugs in the market for HIV/AIDS treatment.

**Figure 30** Pyridine–furan hybrid compounds with 50% reduction in viral titer against adenovirus 7 strain.

<span id="page-24-2"></span>

**Figure 31** Potent antiviral compound **59** with activity against H5N1 influenza virus.

In recent years, antiviral drugs have been developed as a result of the search for viable viral therapeutic approaches. Click chemistry is one of the most effective ways for producing bioorganic molecules, such as antiviral therapeutics. In a recent study, pyridine derivatives were acquainted with propargyl group by *O*-propargylation **58**–**59** ([Figure 31\)](#page-24-2). Cu-catalyzed cycloaddition of azido-sugars with substituted (propargyl)oxypyridines or propargyl sugars with azidoethoxypyridine derivatives resulted in high yields of desired 1,2,3-triazoles. MTT and plaque-reduction assays were

<span id="page-24-3"></span>performed against the H5N1 influenza strain to evaluate antiviral activity. High activity and low toxicity were demonstrated by triazolyl glycoside **58**. The effect of pyridinyl fragment binding to glycosyl triazole moieties on antiviral activity was studied using SAR correlations. Most of the compounds had weakly active to moderately active inhibitory profiles at different concentrations, with the exception of compound **59**, which had the strongest activity. All tested compounds showed dosedependent inhibitory behavior. Low cytotoxicity was observed for compounds **58** and **59**. [200](#page-47-29)

<span id="page-25-0"></span>

**Figure 32** Antiviral GAK inhibitors containing isothiazolopyridine scaffold.

Auxilin 2, also known as cyclin G–associated kinase (GAK), has been demonstrated to impact both the initial and late phases of the viral life cycle, thereby functioning as the master regulator against viral infection. This host-specific strategy offers many advantages, such as development of broad-spectrum antiviral agents and high barriers to resistance. Asquith et al initially discovered SGC-GAK-1 **60**, which has excellent GAK affinity with a  $K_D$  value of 1.9 nm.<sup>[201](#page-47-30)</sup> Later, Jonghe et al developed potent and selective GAK inhibitors **61**–**62** that were basically isothiazolopyridine-type compounds with morpholine residue ([Figure 32](#page-25-0)). These <span id="page-25-4"></span>compounds had high GAK affinity, but were moderately active against dengue and hepatitis C viruses. $202$  Subsequent research showed that the introduction of dimethyl groups to the morpholine residue of **62** had favorable antiviral effects, which led to the discovery of **63**. The compound was active against chikungunya, dengue, and Zika viruses.<sup>203</sup> However, replacing the morpholine residue with carboxamides, alkox-ides, and amines resulted in weak antiviral effects.<sup>204,[205](#page-48-2)</sup>

<span id="page-25-6"></span><span id="page-25-5"></span>Further modifications to the pyridine core of **63** were done to further improve the antiviral effect. The new compounds were highly active against dengue, with GAK-binding affinity

<span id="page-25-3"></span><span id="page-25-1"></span>

<span id="page-25-2"></span>

**Figure 34** Antiviral compounds with high GAK-binding affinity.

in the nanomolar range. For example, compound **64** inhibited GAK strongly [\(Figure 33](#page-25-1)) and was equally potent against dengue.<sup>206</sup>

A novel series of isothiazolopyridines containing 3.4 dimethoxyphenyl residue was also synthesized, $206$  wherein GAK  $IC_{50}$  values were 0.1–0.5  $\mu$ M. Compound 65 had the highest GAK affinity ( $IC_{50} = 0.124 \mu M$ ), whereas compound **66** containing *N*-morpholinyl residue was fivefold less active [\(Figure 34\)](#page-25-2). Diverse structural modifications at the active site of the 6-phenyl moiety's position 4 can, however, be employed to alter antiviral activity.<sup>[206](#page-48-3)</sup>

<span id="page-26-2"></span>Although many pyridine-containing drugs are commercially available to manage HIV/AIDS, further research on the isothiazolopyridine class of compounds could lead to a viable solution for other types of viral infections, such as dengue.

# Anti-inflammatory Drugs and Active Compounds

<span id="page-26-3"></span>Oxicam compounds are used to treat musculoskeletal disorders: acute and chronic inflammation via inhibition of the cyclooxygenase isoforms COX1 and COX2. $207$  The FDA-approved oxicam NSAIDs containing the pyridine moiety are shown in [Figure 35](#page-26-0). These drugs are mainly used to treat musculoskeletal disorders, such as osteoarthritis and rheumatoid arthritis, by relieving painful inflammatory conditions[.208](#page-48-5)

Clonixin ([Figure 36\)](#page-26-1) is another FDA-approved drug and has analgesic and antipyretic effects in chronic arthritic conditions.[69](#page-44-1) For etoricoxib, the FDA needs additional safety data for the approval. It is, however, licensed in >80 countries worldwide. The drug, which is a COX2 inhibitor, is mainly used for the treatment of gout, ankylosing spondylitis, osteoarthritis, psoriatic arthritis, and rheumatoid arthritis.[209](#page-48-6)

<span id="page-26-6"></span><span id="page-26-5"></span>Recently, many bioactive molecules have been reported to deal with inflammatory markers.<sup>210[,211](#page-48-8)</sup> Thirumurugan et al synthesized indole-bearing pyridine derivatives and evaluated their anti-inflammatory activity against rat-paw edema. All compounds had remarkable anti-inflammatory activity, particularly **67**–**68**, which demonstrated significantly higher activity than the standard drug indomethacin [\(Figure 37](#page-27-0)). The analgesic activity of dihydropyridine derivatives was also compared with aspirin. Compounds **68**–**70** had considerably higher analgesic activity[.212](#page-48-9)

<span id="page-26-7"></span>In an attempt to broaden the scope of anti-inflammatory research, Liu et al designed thienopyridine derivatives [\(Figure 38\)](#page-27-1). When subjected to NO-production assays, most of the compounds were able to inhibit NO production. The most effective analogue, **72**, substantially reduced NO production at lower doses (IC<sub>50</sub> = 3.30  $\mu$ M). Anti-inflammatory profiles were further investigated by evaluating TNF $\alpha$ -inhibitory activity of the most potent compound —

<span id="page-26-4"></span><span id="page-26-0"></span>

<span id="page-26-1"></span>Figure 35 FDA-approved oxicam-class NSAIDs for musculoskeletal disorders, such as osteoarthritis and rheumatoid arthritis.

<span id="page-27-2"></span>Figure 38 Thienopyridine derivatives (72-75) with anti-inflammatory and immunomodulatory profiles. IC<sub>50</sub> values correspond to inhibition of NO production on murine RAW264.7 macrophages.

**Figure 39** Highly potent anti-inflammatory compounds.

**72**. Interestingly, compounds with piperazine residue — **74**  and **75** — demonstrated comparable effectiveness. These results indicated that thienopyridine-containing compounds of **72**–**75** may represented a new class of anti-inflammatory drugs that necessitated more attention.<sup>213</sup>

<span id="page-28-1"></span>Yaqoob et al recently reported on highly potent antiinflammatory compounds designed by employing pyridinecontaining isonicotinic acid [\(Figure 39\)](#page-27-2). Remarkable ROSinhibitory activity was observed for compounds **76**–**79**. Compound **76** was one of the most potent anti-inflammatory agents, with IC<sub>50</sub> of 1.42 $\pm$ 0.1 µg/mL.<sup>[214](#page-48-11)</sup>

<span id="page-28-4"></span><span id="page-28-3"></span><span id="page-28-2"></span>The antagonizing hormone glucocorticoid stimulates hepatic glucose synthesis while inhibiting insulinassisted glucose absorption in skeletal muscles and adipose tissue.<sup>215</sup> Glucocorticoidal stimulation, which is coordinated by 11β-HSD2 and 11β-HSD1 enzymes, is often used to measure glucocorticoid target–tissue activity.<sup>[216](#page-48-13)</sup> Enzyme 11-HSD1 is considered to play a crucial role during lipid and glucose metabolism in adipose tissue. Therefore, inhibitors of 11-HSD1 are a novel family of drugs that are being developed to address diabetic complications. The role of 11-HSD1 in the development of insulin resistance and obesity has been shown in several preclinical investigations. Recently, α-glucosidase–inhibitory activity was tested in vitro using a new set of triazole-containing dihydropyridine derivatives. When compared to the acarbose standard (IC<sub>50</sub> = 395.17  $\mu$ M), these compounds showed considerable  $\alpha$ -glucosidase–inhibitory activity (IC<sub>50</sub> = 72.71–283.41 µM). Compounds **80**–**82** ([Figure 40](#page-28-0)) seemed to have the highest inhibitory action against the enzyme, with  $IC_{50}$  values of  $72.71 \pm 1.09$ ,  $73.83$  $\pm 1.17$ , and 85.96 $\pm 1.84$  µM, respectively. To understand the mechanism of action, the most efficient compounds (**80** and **81**) of the series were evaluated using in vitro enzymatic tests to assess their 11β-HSD1 enzyme–inhibitory activity. The mechanism of action of **80** and **81**  was further confirmed using molecular docking analysis, which showed that both compounds bound strongly in the cavity of 11β-HSD1 receptors, resulting in appreciable dock scores, electrostatic energy, and hydrogenbond interactions for the desired molecular complex (both sides and back chain). Overall, compounds **80**  (−9.758) and **81** (−8.595) demonstrated highly stable binding patterns for 11β-HSD1 in molecular docking studies.<sup>[217](#page-48-14)</sup>

<span id="page-28-5"></span>Larijani et al reported excellent α-glucosidase activity for coumarin-fused pyridines ([Figure 41](#page-29-0)). Most of their compounds had  $IC_{50}$  values in the range of 101.0 $\pm$ 2.0 to  $227.3\pm1.4$  μM, whereas the standard drug acarbose had an IC<sub>50</sub> value of  $750.0 \pm 1.5$   $\mu$ M. Compounds **83–85** were the most potent, with IC<sub>50</sub> values of 101.0 $\pm$ 2.0, 111.3 $\pm$ 1.5 and  $114.3\pm1.8$  μM, respectively.<sup>218</sup>

<span id="page-28-6"></span>Although many pyridine-containing NSAIDs are commercially available for musculoskeletal disorders, such as osteoarthritis and rheumatoid arthritis, further research on

<span id="page-28-0"></span>

pyridine- or dihydropyridine-containing oxicams may lead to the development of effective drugs for the cure of acute and chronic inflammation.

# Neurogenic Drugs and Bioactive Compounds

<span id="page-29-2"></span><span id="page-29-1"></span>Neuroprotection may be defined as the maintenance, preservation, and stability of neuronal functions and structures. It is a mechanism for smooth working of the nervous system and prevention of neural damage.<sup>219</sup> The brain is a very sensitive part of body, so remains highly vulnerable to pathogens and damage causing neurodegenerative disorders, such as Parkinson's disease, amyotrophic lateral sclerosis, epilepsy, brain tumors, and Alzheimer's disease.<sup>[220,](#page-48-17)221</sup> These illnesses are main cause of neuronal death, including neural strokes, which are a result of different complications like calciumhomeostasis loss, cytotoxicity, metabolic failure, and oxidative stress[.222](#page-48-19) Many pyridine- or dihydropyridine-containing drugs are being evaluated for the treatment of neurodegen-erative disorders<sup>223</sup> ([Figure 42\)](#page-30-0).

#### <span id="page-29-4"></span><span id="page-29-3"></span>Alzheimer's Disease

<span id="page-29-5"></span>Nimodipine is a wide-spectrum neuroprotective drug that is widely used in Alzheimer's disease, migraine, and posthemorrhagic vasospasm as an anti-ischemic agent.<sup>224</sup> Nimodipine [\(Figure 43](#page-30-1)) is well known for its relaxing potential for cerebral vasculature.<sup>[225](#page-48-22)</sup>

<span id="page-29-6"></span>Alzheimer's disease is a neurodegenerative disorder characterized by memory dysfunction and cognitive impairment. A number of compounds based on pyridine <span id="page-29-7"></span>and dihydroxypyridine have been synthesized and evaluated for their anti-Alzheimer's activity. León et al developed a series of tacrine–dihydropyridine hybrids decorated with pyrin scaffolds.<sup>226</sup> The series was evaluated for inhibitory potential against acetylcholinesterase. Compound **86** had tenfold the activity  $(IC_{50} = 0.0048 \pm 0.001)$  of the donepezil standard (0.049±0.005; [Figure 44](#page-31-0)).

Huperzine A **94** ([Figure 45](#page-31-1)) is well recognized for its neuroprotective properties, which result in enhanced NGF production and expression, which are involved in the functional enhancement of neurons, their survival, and protection against damage in neurodegenerative illnesses (such as Alzheimer's). It protects neurons from glutamate toxicity by decreasing glutamate-induced calcium mobilization. It also protects rat pheochromocytoma cells from oxidative stress caused by hydrogen peroxide. Because oxidative stress exacerbates Alzheimer's neurodegeneration, huperzine A **94** is widely used to treat Alzheimer's complications[.227](#page-48-24)

<span id="page-29-9"></span><span id="page-29-8"></span>Recently, a dihydropyridine derivative with pyridinium moiety **87** was found to be highly active as a gene-transfection agent and displayed excellent mitochondrion-targeted antioxidant activity.<sup>228</sup> It was found to play an important role in protection against neural injuy [\(Figure 46\)](#page-31-2), and causeed increased expression of proteins in the hippocampus and cerebral cortex. It was found that increased expression of the GAD67 enzyme in hippocampus converted the glutamate to GABA, and GABA was found to protect the brain from neural injury. It regulated the development of spatial memory, and via synthesis of GABA it balanced neurotransmitters, consolidation, and stability of memory. Owing to its memory-improvement and neural protection abilities, it can be used in the treatment of Alzheimer's disease.

Dihydropyridine derivatives with pyridinium moiety can be a viable solution for the cure Alzheimer's, since they are able to enhance the expression of crucial proteins in the hippocampus and cerebral cortex. In coming years, extensive research in this type of compound is anticipated.

#### Parkinson's Disease

<span id="page-29-10"></span>Pyrazoline-containing pyridine derivatives have been reported to display antiparkinsonian activity.<sup>229</sup> For example, compounds **88** and **89** have significant antiparkinsonian activity, with 0.8 relative potency compared to the reference drugs benzatropine and voltaren ([Figure 47](#page-32-0)).

Several dihydropyridines have amino acids in their structure and are peptidomimetic in nature. The most

<span id="page-30-0"></span>

**Clioquinol** (Under clinical studies for Alzheimer's)

**Nilotinib** (Under clinical studies for Parkinson's)

**Mastinib** (Under clinical studies for Amyotrophic Lateral Sclerosis)

**Nilvadipine** (Under clinical studies for Alzheimer's)

**Dolutegravir** (Under clinical studies for Amyotrophic Lateral Sclerosis)

**Figure 42** Pyridine- or dihydropyridine-containing drug-repurposing candidates for treatment of neurodegenerative diseases.

<span id="page-30-1"></span>

**Figure 43** Structure of the wide-spectrum neuroprotective drug nimodipine.

studied are glutapyrone **90** and tauropyrone **91**  [\(Figure 48\)](#page-32-1). Both these compounds protect cerebellar granule cells from damage by lowering lactate dehydrogenase, thus avoiding ischemia/hypoxia (lack of oxygen and glucose) and glutamate excitotoxicity. Tauropyrone **91**  can be used for the treatment of Parkinson's disease, as it suppresses the inflammatory process in rats in a Parkinson's 6-hydroxydopamine model at 6.25 g/L per day for 7 and 14 days. Tauropyrone **91** (1 mg/kg) shows dual actions in the brain. In some cases, it shows inflammatory and proapoptotic effects, but in azidothymidine toxicity, it acts as anti-inflammatory and antiapoptotic agent. The amino acid–containing monocyclic dihydropyridines represent a new atypical group of DHPs, and data have shown their neuromodulatory potential and normalizing effect on protein expression in the brain. $230-233$ 

<span id="page-30-2"></span>Although pyrazoline-containing pyridine derivatives have been reported to display antiparkinsonian activity,

<span id="page-31-0"></span>

<span id="page-31-2"></span>

Figure 46 Compound 87 is capable of increasing expression of the GAD<sub>67</sub> enzyme in the hippocampus.

many reports in the literature have suggested that non– calcium agonistic 1,4-dihydropyridine derivatives demonstrate remarkable neuroprotective effects, thus holding great potential for future drug design against Parkinson's disease.

#### Cerebral Ischemia

Cerebral ischemia is also a neuronal disorder in which many noxious by-products and free radicals are generated, resulting in enzymatic activity being altered, which results in a breakdown of cellular phospholipids, proteins, and nucleic acids. Cerebral edema is a complication that occurs due to the overexpression of AQP4 whereby abundant water enters the brain and the swollen brain is compressed against the skull. This increased pressure in the cranium causes herniation and brain ischemia, leading to death. This condition is treated with piroxicam [\(Figure 49\)](#page-32-2), which has inhibitory effects on AQP4 (the most abundant water channel in the brain). Pyridine ring– containing piroxicam **92** binds with AQP4, and in this way regulates it in brain to avoid cerebral ischemia and edema[.234](#page-48-28)

#### <span id="page-31-3"></span>Schizophrenia

Schizophrenia is a mental condition marked by behavioral, neurochemical, and morphological disorders. Antipsychotics that operate on molecular targets other than monoaminergic receptors have not yet been produced, despite significant progress in medication development for schizophrenia. GABAergic dysfunction may be implicated in this disease.<sup>[235](#page-49-0)</sup> Marcinkowska et al recently discovered the imidazopyridinetype neuroprotective agent **93** [\(Figure 50](#page-32-3)), which shows potential affinity for serotonin  $5HT_2$  and  $5HT_x$  receptors and antipsychotic-like activity. Compound **93** also shows positive allosteric modulator properties, high metabolic stability, and no hepatotoxicity[.235](#page-49-0)

<span id="page-31-6"></span><span id="page-31-5"></span><span id="page-31-4"></span>*Senna* spp. are a celebrated source of natural alkaloids of the piperidine and pyridine classes.<sup>[236,](#page-49-1)237</sup> Francisco et al isolated five new pyridine-containing alkaloids [\(Figure 51\)](#page-33-0) from *Senna* and *Cassia* spp.: 8′-multijuguinol **95**, 7′-multijuguinol **96**, methyl multijuguinate **97**, 12′ hydroxy-8′-multijuguinol **98**, and 12′-hydroxy-7′-multijuguinol **99**, which were isolated from *Senna multijuga*  leaves. All these compounds had acetylcholinesterase-inhibitory activity comparable to the standard drug physostigmine. SAR studies have suggested that hydroxypyridine moiety is the key interaction site responsible for this activity, whereas the alkyl side chain also influences the acetylcholinesterase-inhibitory effect of the alkaloids.<sup>236</sup> A summary of the neuroprotective compounds with their

potential applications and tentative mechanisms is presented in [Table 2](#page-33-1).

# Anticancer Drugs and Bioactive **Compounds**

Cancer is considered a major challenge to public health. There are many pyridine-containing drugs in the FDA database [\(Figure 52](#page-34-0)), eg, axitinib — a tyrosine kinase inhibitor — developed by Pfizer. For the treatment of cancer, other kinase inhibitors containing the pyridinering system are shown in [Figure 53.](#page-34-1)

<span id="page-32-4"></span>Recently, the effectiveness of chemotherapeutic agents has been severely limited by tumor resistance.<sup>[238](#page-49-3),[239](#page-49-4)</sup> In a very recent study, pyridine–thiazole hybrid compounds were studied by Alqahtani et al. These hybrids contained (hydrazonomethyl)phenoxy-acetamide spacers, and novel compounds were evaluated for their cytotoxicity potential against normal fibroblast cells (WI38), breast cancer (MCF7), laryngeal carcinoma (Hep2), prostate cancer (PC3), and liver carcinoma (HepG2). The drug 5-fluorouracil (5-Fu) was employed as the standard during these experiments. Promising anticancer activity against the HepG2 and MCF7 cell lines was reported for compounds

apoptosis. The excellent anticancer capabilities of benzylpyridinium-bearing dihydropyridines might be helpful against MDR cancer strains. However, to gain better knowledge of their mode of action, further in-depth mechanistic validation is still needed for these types of compounds.[243](#page-49-8)

<span id="page-37-2"></span>Naglaa et al recently designed a series of pyridinecontaining anticancer agents [\(Figure 59\)](#page-36-2). The newly synthesized compounds were investigated for in vitro growth activity against mammary-gland carcinoma (MCF7) and human hepatocellular carcinoma (HepG2) cell lines. Doxorubicin, an anticancer drug, was employed as a comparative standard under the same conditions. Against HepG2 and MCF7, most of the newly synthesized compounds showed significantly potent anticancer activity. The derivatives **114**–**116** displayed remarkable activity. To further confirm the hypothesized mechanism, molecular docking studies were conducted to evaluate affinity between the compounds and their binding energy with the enzyme. For potent compounds, the calculated binding <span id="page-37-3"></span>energies were in good agreement with their activity against the MCF7 and HepG2 cell lines. $244$ 

Recently, Eman et al reported an important contribution toward new anticancer agents by developing a series of tetralin–pyridine hybrids, starting from 2-(pyridin-2-yl [oxy])acetohydrazide in appreciable yields ([Figure 60\)](#page-37-0). MTT assays were employed to evaluate the cytotoxic activity of these compounds against human MCF7 and HCT116 cells. IC<sub>50</sub> values were 7.7–9.0  $\mu$ M against HCT116 cancer cells, comparable to the standard drug doxorubicin ( $IC_{50}$  = 8  $\mu$ M). The derivative 117–119 showed IC<sub>50</sub> values of 21.0, 33.3, and 60.3 µM, respectively, against MCF7 cells. It can tentatively be assumed that a tetralin–pyridine backbone is an effective antitumor pharmacophoric moiety against MCF7 cells. These findings suggest that all the tested compounds are more active against human colon cancer cells than human breast cancer cells.<sup>[245](#page-49-10)</sup>

<span id="page-37-4"></span>Phosphodiesterases (PDEs) have been recognized as important targets in cancer therapy, due to their critical role in apoptosis induction and inhibition of tumor-cell

<span id="page-37-1"></span>

**Figure 61** Highly potent anticancer compound with PDE3-inhibitory effect.

<span id="page-38-0"></span>

**Figure 62** Antitumor agents with telomerase-inhibitory effects.

growth. Some nonselective PDE inhibitors, eg, aminophylline and theophylline, have been recognized as growth regulators in various carcinoma cell lines, suggesting a potential role as anticancer drugs for PDE inhibition. A range of imidazoaryl-containing dihydropyridine compounds and their 2-oxo isostere derivatives was synthesized and evaluated as PDE inhibitors by Atieh et al. The cytotoxic effect was also checked for the HeLa and MCF7 cell lines. An extraordinarily high PDE3A inhibitory effect was demonstrated by compound  $120$ , with  $IC_{50}$  of 3.76 ±1.03 nM ([Figure 61\)](#page-37-1). Compound **89** also displayed significantly high cytotoxicity effects against MCF7 and HeLa cells  $(IC_{50} 50.18 \pm 1.11$  and  $34.3 \pm 2.6 \mu M$ , respectively). The strong association between  $IC_{50}$  values of cytotoxicity and PDE3A inhibition support the notion that PDE3 inhibitors could be used as cytotoxic entities. According to SAR investigations and docking studies, hydrophobic interactions were found to be equally important in the formation of hydrogen bonds intended for PDE3 inhibition and cytotoxic effects of proposed derivatives.<sup>246</sup>

<span id="page-38-2"></span>The crucial role of telomerase in tumor growth makes it a promising target for cancer treatment and other agerelated illnesses. Telomere and telomerase are known to be linked to the progression of gastric cancer. Xin-Hua and others synthesized flavone containing 2-chloro-pyridine derivatives for telomerase inhibition ([Figure 62\)](#page-38-0). Modified telomeric repeat-amplification protocol assays were used to evaluated the telomerase-inhibitory effect of the compounds, and **121** and **122** showed significant activity against the SGC7901 gastric cancer cell line, with  $IC_{50}$ of  $18.45\pm2.79$   $\mu$ g/mL and  $22.28\pm6.26$   $\mu$ g/mL, respectively. In order to determine the probable binding mode, dockingsimulation studies were performed at 3DU6-active sites. Compound **122** was a more effective inhibitor of telomerase by binding with the telomerase-active site. $247$ 

<span id="page-38-3"></span>Fatma et al also reported disubstituted pyridines [\(Figure 63\)](#page-38-1) and studied their anticancer activity against the HepG2 cells. Compounds **123**–**125** were found to have promising activity comparable to standard drugs and 5- fluorouracil.<sup>[248](#page-49-13)</sup>

<span id="page-38-5"></span><span id="page-38-4"></span>In 2016, pyridine–pyrimidine hybrid ring system–containing compounds were screened at 10 µM against various cancer-cell lines,<sup>249</sup> ande compound **126** [\(Figure 64](#page-39-0)) showed promising inhibitory effects against the NCI60 cell lines, with  $IC_{50}$  of 1.40  $\mu$ M for UO31, 1.55  $\mu$ M for

<span id="page-38-1"></span>

<span id="page-39-0"></span>

<span id="page-40-3"></span>[1,5-a]pyridinylpyridines.[253](#page-49-18) Compound **134** had remarkably high anticancer effects in these cell lines ([Figure 68](#page-40-1)).

<span id="page-40-4"></span>In diphenyl-1-(pyridin-3-yl)ethylphosphonates, $254$  the compounds **135** and **136** also demonstrated cytotoxic effect against MCF7 and HepG2 cells ([Figure 69](#page-40-2)).

Pyridine and dihydropyridine are considered attractive scaffolds for anticancer drug development, since many drugs containing these moieties are already in the market, having shown remarkable results. Rational design of new anticancer drugs can be achieved by incorporating these scaffolds into the backbone of bioactive molecules, followed by their analysis with computational methods to predict highly potent

candidates. Drug repurposing of existing pyridine- and dihydropyridine-containing pharmaceuticals should also be explored to accelerate the discovery of new anticancer drugs.

# **Conclusion**

The present review is a critical analysis of various drugs and research on the design and development of assorted derivatives of pyridine- and dihydropyridine-based compounds. They have been characterized on the basis of their pharmacological activity. Specific structural features pertinent to particular activity have also been discussed. The pyridine core has far greater tractability to produce anti-infectious and anticancer agents. This is evident from the fact that the FDA has recently approved many pyridine-containing antibiotics, such as ceftaroline fosamil (2010), tedizolid (2014), ceftazidime (2015), and delafloxacin (2017). In the database, one can also find isoniazid, ethionamide, and prothionamide, which are highly effective against mycobacteria for the treatment of tuberculosis. Combination of pyridine scaffolds with oxazolidinone hold great promise in this regard, since many such compounds have recently appeared in contemporary literature with remarkable antibacterial effects. For example, the compounds **23**–**25** have potent activity against a wide range of drug-resistant bacteria, as well as *M. catarrhoides* and *H. influenzae*, both in in vitro and in vivo evaluations. The FDA database also contains many pyridine-containing antiviral drugs, such as nevirapine, tipranavir, doravirine, and indinavir, which are being employed to manage HIV infection. During the last 10 years, many isothiazolopyridine-based compounds, such as **61**–**66**, were developed as selective GAK inhibitors to thwart the initial and latestage viral life cycle. Pyridine-containing oxicam compounds were also found to be promising against musculoskeletal disorders, such as osteoarthritis and rheumatoid arthritis. For the treatment of cancer, pyridine was the integral part of numerous FDA-approved kinase inhibitors, such as acalabrutinib, neratinib, abemaciclib, alpelisib, lorlatinib, and pexidartinib, whereas many pyrazolo<sup>[3,4-*b*]pyridine–containing com-</sup> pounds (**102**–**106**), ha exceptionally high antiproliferative activity (IC<sub>50</sub> = 0.0091-0.0211  $\mu$ M) against MCF7 cells, while the standard drug doxorubicin had an  $IC_{50}$  of 0.099 µM. In arene–ruthenium complexes with pyridine scaffolds, Süss-Fink et al found highly potent anticancer effects, with  $IC_{50}$  values being in the submicromolar range. Pyridine-containing ruthenium compounds hold great promise for the replacement of cisplatin-based anticancer drugs. Dihydropyridine ring–containing drugs mostly act as calcium-channel blockers and ware frequently employed for the treatment of hypertension and heart-related problems. Such drugs include nimodipine, ciclopirox, efonidipine, nifedipine, milrinone, and amrinone. Cholesterol-lowering compounds (**18**–**22**) containing dihydropyridine rings were developed due to different antidyslipidemic and antioxidant effects of such a scaffold. Dihydropyridine-containing **80**–**82** ware able to inhibit 11β-HSD1 for the potential cure of diabetes mellitus. In the literature, one can also find numerous pyridine- or dihydropyridinecontaining compounds (**86**–**94**) for the potential treatment of neurodegenerative disorders, along with many drugs-repurposing examples, such as dolutegravir, mastinib, nilvadipine, nilotinib, clioquinol, imatinibs. Despite years of research, further work is still warranted to optimize their effects and understand

their mechanisms of action. In summary, pyridine- and dihydropyridine-containing compounds combined with broadened chemical space will help medicinal chemists to design bioactive molecules for specific targets. Briefly, in view of the colossal structural diversity of pyridine- and dihydropyridinecontaining compounds, the existing literature barely scratches the surface of possibilities for their pharmacological application. Therefore, the interest in them is unlikely to die out anytime soon. We will see an increase in the structure, application, and diversity of pyridine- and dihydropyridine-containing compounds, with great potential for new cardiovascular, antiinflammatory, anti-infectious, neurogenic, and anticancer drugs containing the two heterocycles in the forthcoming decade.

#### **Drug Design, Development and Therapy [Dovepress](https://www.dovepress.com)**

**Publish your work in this journal** 

Drug Design, Development and Therapy is an international, peerreviewed open-access journal that spans the spectrum of drug design and development through to clinical applications. Clinical outcomes, patient safety, and programs for the development and effective, safe, and sustained use of medicines are a feature of the journal, which has also

been accepted for indexing on PubMed Central. The manuscript management system is completely online and includes a very quick and fair peer-review system, which is all easy to use. Visit [http://www.](http://www.dovepress.com/testimonials.php) [dovepress.com/testimonials.php](http://www.dovepress.com/testimonials.php) to read real quotes from published authors.

**Submit your manuscript here:** https://www.dovepress.com/drug-design-development-and-therapy-journal
