Abstract: Safflower seed extract (SSE) contains characteristic polyphenols and serotonin derivatives (*N*-(*p*-coumaroyl) serotonin and *N*-feruloylserotonin), which are reported to inhibit oxidation of low-density lipoprotein (LDL), formation of atherosclerotic plaques, and improve arterial stiffness as assessed by pulse wave analysis in animal models. The effects of long-term supplementation with SSE on arterial stiffness in human subjects were evaluated. This double-blind, placebo-controlled study was conducted in 77 males (35–65 years) and 15 postmenopausal females (55–65 years) with high-normal blood pressure or mild hypertension who were not undergoing treatment. Subjects received SSE (70 mg/day as serotonin derivatives) or placebo for 12 weeks, and pulse wave measurements, ie, second derivative of photoplethysmogram (SDPTG), augmentation index, and brachial-ankle pulse wave velocity (baPWV) were conducted at baseline, and at weeks 4, 8, and 12. Vascular age estimated by SDPTG aging index improved in the SSE-supplemented group when compared with the placebo group at four ($P = 0.0368$) and 12 weeks ($P = 0.0927$). The trend of augmentation index reduction ($P = 0.072$ versus baseline) was observed in the SSE-supplemented group, but reduction of baPWV by SSE supplementation was not observed. The SSE-supplemented group also showed a trend towards a lower malondialdehyde-modified-LDL autoantibody titer at 12 weeks from baseline. These results suggest long-term ingestion of SSE in humans could help to improve arterial stiffness.

Keywords: safflower, serotonin derivatives, antioxidants, augmentation index, pulse wave velocity

Introduction

In Korea and other Asian countries, safflower (*Carthamus tinctorius L.*) seeds have been used as a traditional food or herbal medicine for the treatment of rheumatism and osteoporotic fractures.^{1,2} Among the polyphenols, two major serotonin derivatives, *N*-(*p*-coumaroyl) serotonin (CS) and *N*-feruloylserotonin (FS), have been identified as the characteristic components of defatted safflower seed extract (SSE).^{3–5} Serotonin derivatives have been shown to have potent antioxidant property,^{4,5} antitumor activity,^{1,6} fibroblast proliferation stimulating activity,⁷ and protective effects against postischemic myocardial dysfunction.⁸ SSE, as well as serotonin derivatives, have been reported to have the ability to reduce atherosclerotic lesions in apolipoprotein E-deficient mice and in Kurosawa and Kusanagi-hypercholesterolemic (KHC) rabbits.^{5,9} Katsuda et al reported that SSE or serotonin derivatives reduced pulse wave velocity (a clinical parameter of noninvasive arterial stiffness) and ameliorated the pressure-strain elastic modulus (index of distension of the wall) in the aorta of KHC rabbits.⁹

Parameters of arterial stiffness are associated with aging and increase the relative risk of atherosclerosis. Noninvasive pulse wave analysis methods, such as pulse wave velocity, augmentation index, and second derivative of the fingertip photoplethysmogram (SDPTG) have been developed to measure arterial stiffness. These methods have been postulated to predict cardiovascular events.^{10–17} Several clinical studies have reported the use of drugs for the treatment of arterial stiffness. However, there are few reports on the use of functional food ingredients for this purpose. In a human pilot study, SSE supplementation was found to have a favorable effect on brachial-ankle pulse wave velocity (baPWV) in individuals with relatively high blood pressure (BP) or with a relatively high baPWV.¹⁸ Therefore, we investigated the effects of SSE on arterial stiffness in males and postmenopausal females with high-normal BP or mild hypertension. The endpoints were baPWV, augmentation index at the radial artery, and SDPTG.

Material and methods

This study was conducted according to the guidelines laid down in the Declaration of Helsinki, and all procedures involving human subjects were approved by the Clinical Trial Ethics Committee of the Shinanozaka Clinic, Tokyo, Japan. Written informed consent was obtained from all subjects.

Study protocol and subjects

This 12-week, double-blind, placebo-controlled study was conducted in 77 males (35–65 years) and 15 postmenopausal females (55–65 years) with high-normal BP or mild hypertension. Before the main clinical examination, two prior measurements were carried out in enrolled subjects according to the following inclusion criteria: baPWV > 1250 cm/sec and rate of baPWV change between the two prior measurements being <7%. Subjects with a history or presence of cardiovascular disease, on medication for hypertension, hyperlipidemia, or diabetes mellitus, or medication for inflammatory disease, such as arthritis, dermatitis, and hepatitis, were excluded from the study. Subjects received three capsules of SSE (11.7 mg of serotonin derivatives [CS + FS] per capsule) or placebo (180 mg of lactose per capsule) twice a day for 12 weeks (total daily serotonin derivative intake 70 mg/day). Measurements of pulse wave analysis at baseline, and at weeks 4, 8 and 12, and blood sampling at weeks 0 and 12 were conducted in the morning after an overnight fast. Measurements were conducted twice and averaged to provide a daily mean value. During the treatment

period, subjects were advised not to take medicines, antioxidant supplements, polyunsaturated fatty acids, and food for specific lowering of high BP.

Preparation of SSE

Safflower seeds were provided by ADRI Limited (Sofia, Bulgaria). They were defatted by compression and extracted with 50% (v/v) ethanol. Extracted solutions were filtered and concentrated in vacuo. Water was added to the concentrated solution; this was kept overnight at room temperature. The precipitate was mixed with the eluted supernatant, which was loaded onto the adsorption column. The precipitate was then eluted using 50% (v/v) ethanol. After concentration in vacuo, the samples were freeze-dried. The obtained solid was crushed and filtered. Macronutrient and serotonin derivative compositions of the SSE are shown in Table 1. The SSE powder was filled in hard gelatin capsules and administered as an experimental dietary supplement.

Measurement procedures

BP and baPWV were measured simultaneously using an automated device, ie, pulse wave velocity/ABI (BP-203RPE II; Omron Colin, Tokyo, Japan). The detailed methodology for measuring baPWV has been described elsewhere.¹⁸ In brief, four pneumatic pressure cuffs, two electrocardiographic electrodes, and a microphone for detecting heart sounds were attached to both the arms and ankles, both wrists, and on the left edge of the sternum to record the volume waveform for the brachial and ankle arteries. baPWV was automatically calculated as the length of an arterial segment between the brachium and ankle, which was automatically calculated from body height divided by transit time of the pulse wave. The mean of the left- and right-sided measurements of baPWV and BP were calculated to obtain a daily value. The method was validated in a previous report, and the inter- and intraobserver coefficients of variation were 8.4% and 10.0%, respectively.¹⁹

Table 1 Composition of safflower seed extract

	SSE
Energy (kJ/100 g)	1703.7
Protein (g/100 g)	19.1
Fat (g/100 g)	6.2
Carbohydrate (g/100 g)	68.0
Ash (g/100 g)	3.0
Dietary fiber (g/100 g)	1.3
CS (mg/g)	34.9
FS (mg/g)	49.3

Abbreviations: CS, *N*-(*p*-coumaroyl) serotonin; FS, *N*-feruloylserotonin; SSE, safflower seed extract.

Radial augmentation index was measured and calculated from the pulse wave using a semiautomatic pulse wave analyzer (HEM-9000 AI; Omron Colin). In brief, the arterial pulse wave was noninvasively obtained from the left radial artery by tonometric tracing. The 8 mm wide tonometric sensor comprised 40 arrayed microtransducers. The most appropriate microtransducer was automatically selected for optimal measurement. The hold-down pressure of the sensor head was automatically adjusted for each subject. Pulse waves were measured for 30 sec and digitized at 500 Hz. Radial augmentation index was calculated as the ratio of the late systolic pressure to pulse pressure, ie:

$$\frac{\text{Late systolic BP} - \text{diastolic BP}}{\text{systolic BP} - \text{diastolic BP}} \times 100 (\%)$$

Radial augmentation index was automatically calculated using a fourth-order differential equation for a radial arterial waveform (HEM-9000 AI). Measurement was carried out with subjects in the sitting position. The coefficients of variation for intra- and interobserver measurements for the radial aging index using this device were 4.3% and 2.5%, respectively.²⁰

SDPTG was measured by fingertip photoplethysmography (SDP-100; Fukuda Denshi, Tokyo, Japan). The sensor was placed on the cuticle of the second digit of the left hand. During the measurement, subjects rested on a bed in a quiet room. The SDPTG consists of five specific waves, ie, a, b, c, and d systolic waves, and an e wave that is diastolic. Ratios for the following parameters were obtained: b/a, d/a, and SDPTG aging index (SDPTG-AI; (b - c - d - e)/a). Vascular age was calculated for males as $43.5 \times \text{SDPTG-AI} + 65.9$ years and for females as $41.7 \times \text{SDPTG-AI} + 61.8$ years.¹⁵ Reproducibility of the SDPTG has been previously reported, with an intraobserver repeatability of 8%.²¹

Biochemical parameters

Plasma glucose and serum lipids, ie, total cholesterol, low-density lipoprotein (LDL) cholesterol, high-density lipoprotein (HDL) cholesterol, and triglycerides, were measured at SRL Inc. (Tokyo, Japan) using its standard laboratory protocols.

Oxidative stress status

Serum autoantibody titers to malondialdehyde-modified LDL (anti-MDA-LDL) were measured by enzyme-linked immunosorbent assay (ELISA).¹⁸ Oxidized LDLs in serum were measured as 4E6 monoclonal antibody-reactive substances using an oxidized LDL competitive ELISA kit (Merckodia, Uppsala, Sweden). The parameters were measured at SRL Inc.

Proinflammatory markers

The serum-soluble form of vascular cell adhesion molecule-1 (sVCAM-1), the soluble form of intercellular adhesion molecule-1 (sICAM-1), and monocyte chemoattractant protein-1 (MCP-1) were measured at SRL Inc. using Quantikine Immunoassay kits (R&D Systems, Minneapolis, MN).

Statistical analysis

Results are represented as mean \pm standard deviation unless otherwise stated. All data analyses were conducted using the Statistical Software for Social Sciences (15.0.1 (SPSS, Inc., Chicago, IL). Changes from baseline between the groups were compared using analysis of covariance, adjusting for each baseline result. Comparison with baseline (0 week) in the same group was conducted by paired *t*-test.

Results

Subject characteristics

Clinical characteristics of subjects included in this study are presented in Table 2. Before administration of the test material, baPWV in the placebo group was significantly higher than that in the SSE-supplemented group ($P = 0.0231$). Other factors were not significantly different between the two groups. None of the subjects had serious conditions, such as pulmonary or renal disease.

During the study, three subjects in the SSE-supplemented group were excluded from analysis (two due to failure to

attend the study, and one due to development of hyperuricemia). Statistical analysis of the SSE-supplemented group was conducted in 44 and 43 subjects after eight and 12 weeks of SSE supplementation, respectively.

Effects of SSE on BP and arterial stiffness

Table 3 shows values and changes in least-squares mean of BP and arterial stiffness parameters from baseline, after ingestion of test meals at weeks 4, 8, and 12. At four weeks, the SSE-supplemented group showed lower SDPTG-AI and b/a ($P = 0.0620$ and 0.0507 , respectively) than the placebo group. Vascular age was significantly lower in the SSE-supplemented group at four weeks ($P = 0.0368$) and remained

significantly lower at 12 weeks ($P = 0.0927$) than in the placebo group. There were no significant differences in systolic BP, diastolic BP, baPWV, and augmentation index between the two groups.

Blood analysis

Biochemical parameters, oxidative stress, and proinflammatory markers in blood at baseline and 12 weeks after ingestion of test meals are presented in Table 4. Significant variations in LDL cholesterol at 12 weeks from baseline were observed in the SSE-supplemented group. There was no significant change from baseline for other biochemical parameters in either group at 12 weeks. No significant changes in oxidative

stress markers (oxidized LDL and anti-MDA-LDL) or proinflammatory markers (sICAM-1, sVCAM-1, and MCP-1) were observed in either group. Anti-MDA-LDL in the SSE-supplemented group at 12 weeks tended to be lower than at baseline ($P = 0.078$ versus baseline, SSE group).

Discussion

The effect of SSE ingestion on arterial stiffness was investigated in subjects with high-normal BP or mild hypertension in this placebo-controlled, double-blind study. In a pilot study, four weeks of SSE supplementation was found to exert a favorable effect on baPWV in individuals with relatively high BP, or with a relatively high baPWV.¹⁸ Therefore, in this study, to determine the effect of SSE on baPWV precisely, we enrolled subjects on the basis of the two aforementioned inclusion criteria, and a prolonged treatment period of 12 weeks of SSE supplementation did not have a significant effect on baPWV. The nature of pulse wave velocity is significantly influenced by BP, and a pilot study suggested that SSE affects vascular function by reducing BP, which resulted in the reduction of baPWV. However, it is unclear whether reduction in BP was due to SSE supplementation, because the pilot study was an open-label, non-placebo-controlled study. In addition, baPWV seems to be primarily associated with structural distensibility in large arteries, and long-term treatment would be required to improve baPWV. Treatment with drugs (eg, angiotensin II receptor blockers, antidiabetic agents, and eicosapentaenoic acid) were continued for >six months in several clinical studies of baPWV.^{22–25} We suggest that a prolonged treatment period is required to reach definitive conclusions about the effect of SSE on baPWV.

SDPTG is one of the alternative methods for assessment of arterial stiffness, and this method can be used to estimate vascular age.¹⁶ It is noninvasive and easy for patients to undergo, and we consider that SDPTG is a good parameter of arterial stiffness. Some SDPTG quantifiers were found to be closely correlated with ascending aortic augmentation index, age, and other atherosclerotic risk factors.^{14–17} The SSE-supplemented group showed significant reduction in vascular age, as estimated by SDPTG-AI at four weeks, and showed a lower vascular age than that of the placebo group at 12 weeks. In addition, the effects of SSE were more prominent in a subgroup aged 40–59 years, although the baseline characteristics of each subgroup are similar to those of all subjects (Tables 5 and 6). The age group is a putative core target of metabolic syndrome, and a remarkable change with age has been reported for SDPTG.²⁶ Because measurement of SDPTG is performed in peripheral vessels, it may be affected more by the peripheral artery characteristics than by pulse wave velocity. Therefore, SSE might ameliorate peripheral arterial properties and be able to detect the effects of short-term treatment.

The a and b waves corresponded to the early systolic component and the d wave corresponded to the late systolic component of the SDPTG. Therefore, the b/a ratio is considered to be a marker of the distensibility of large arteries (which is little affected by the reflection wave), and the d/a ratio is closely related to late systolic pressure augmentation in the ascending aorta (and hence regarded as a marker of wave reflection intensity). Increase in the b/a ratio and decrease in the d/a ratio are associated with aging. The SSE-supplemented group showed a tendency towards a decreased b/a ratio ($P = 0.0507$ compared with the placebo group at

four weeks). This may indicate improvement in distensibility of the large arteries by SSE supplementation. Katsuda et al showed that the elasticity of large arteries improved in KHC rabbits after four weeks of SSE treatment,⁹ and the results of their study are consistent with those of our study with regard to the effect of SSE. However, the lack of effect of SSE on baPWV, mainly reflected in the large arteries, is considered to contradict the results of b/a, as described above. This discrepancy needs to be resolved in the future.

Although there was no difference between the placebo and SSE-supplemented groups with respect to augmentation index, there was a tendency towards a reduction in augmentation index in the SSE-supplemented group at 12 weeks ($P = 0.072$ compared with baseline). The augmentation index was obtained from the central arterial waveform as the ratio of augmentation pressure to total pulse pressure. The augmentation index can also be obtained from the radial arterial

waveform, and the radial augmentation index can provide information on vascular aging and arterial stiffness. Our findings of improvements in vascular age as estimated by SDPTG-AI and the augmentation index could suggest that supplementation with SSE decreases vascular aging and the risk of cardiovascular disease.

In a pilot study, Koyama et al used a daily serotonin derivative dose of 290 mg/day.¹⁸ However, in our study we used a daily serotonin derivative dose of 70 mg/day. The dose discrepancy between the studies could be due to the presence or absence of serotonin derivative glycosides as active compounds in SSE. We consider the effect of serotonin derivatives on arterial stiffness to be substantially dependent on aglycon type, because the bioavailability of serotonin derivative glycosides was found to be lesser than that of aglycons in rats.²⁷ Therefore, we only analyzed the intake of serotonin derivative aglycons in this study.

Reactive oxygen species in the vessel wall have been considered to be one of the most important causes of vascular dysfunction. The oxidative modification of LDL has been shown to play a major role in the genesis of atherosclerosis. Antioxidative dietary components, such as polyphenols, have recently attracted considerable attention because they were found to be effective for the prevention of cardiovascular disease.^{28,29} SSE contains some serotonin derivatives, mainly CS and FS, which have been reported to act as potent free radical scavengers.^{4,5} Koyama et al showed that both intact and conjugated forms of CS and FS were detectable in the plasma of apolipoprotein E-deficient mice fed a diet containing SSE. Long-term supplementation of serotonin derivatives inhibited CuSO₄-induced plasma lipid oxidation ex vivo and decreased the plasma titer of autoantibodies to oxidized LDL and plasma lipid peroxides in apolipoprotein E-deficient mice.⁵ Significant reductions in the levels of circulating oxidized LDL, anti-MDA-LDL, and urinary 8-isoprostane were observed after a four-week administration of SSE in a human pilot trial.¹⁸ In the present study, the anti-MDA-LDL titer in the SSE group was found to be lower than that in the

Table 6 Effects of SSE supplementation on vascular age in a subgroup aged 40–59 years

		Measurement value		Least-squares mean change from baseline (95% CI)		
		Placebo group (n = 36)	SSE group (n = 34)	Placebo group	SSE group	P
Vascular age (y)	baseline	54.45 ± 11.02	53.10 ± 12.73			
	4 w	57.72 ± 10.23	51.96 ± 13.60	3.39 (0.74 to 6.04)	-1.53 (-4.30 to 1.23)	0.0126
	8 w	57.65 ± 10.39	52.11 ± 12.15	3.25 (0.78 to 5.73)	-1.97 (-4.60 to 0.65)	0.0052
	12 w	56.56 ± 11.33	52.21 ± 12.43	2.11(-0.39 to 4.61)	-2.14 (-4.84 to 0.55)	0.0241

placebo group, although reduction of oxidized LDL by SSE was not detected. These data suggest that SSE could inhibit oxidized LDL formation and oxidized LDL-mediated vascular injury, and that this effect contributes to amelioration of arterial stiffness. Reduction in the level of LDL cholesterol at 12 weeks was also observed in the SSE group. However, the hypocholesterolemic effect of SSE or serotonin derivatives have not been confirmed reproducibly in animal and human studies.^{5,18} In addition, there is a possibility that other lipid-lowering diets influenced the results. However, we could not evaluate this possibility because we were not able to determine whether or not the subjects took a particular diet that lowers lipids. The association of hypocholesterolemic activity with the effect of SSE on arterial stiffness needs to be carefully assessed in the future.

Takimoto et al reported that CS and FS show direct vascular relaxation effects in the thoracic aorta and femoral artery of rats.^{29,30} Piga et al reported that CS and FS exert an inhibitory effect on short-term high glucose-induced upregulation of mRNA and proteins of adhesion and migration factors, and the consequent adhesion and migration of monocytes to endothelial cells.³¹ These effects may also contribute to amelioration of arterial stiffness by SSE supplementation.

This study had some limitations. First, we could not analyze smoking status in our subjects, which is an important avoidable risk factor for arterial stiffness, although subjects were advised not to smoke on the day of pulse wave analysis. Second, baPWV was significantly higher and systolic BP was marginally higher at baseline in the placebo group in this study. We do not know the exact reason for this. Third, we enrolled males aged 35–65 years and postmenopausal females aged 55–56 years in this study, and age and gender are the first variables that limit the application of such techniques.³² The consideration of the effects of SSE is limited to the group described above.

Although arterial stiffness parameters have been postulated to predict cardiovascular events, there are few interventional studies on the effect of functional food ingredients. We believe that this study may provide information regarding the clinical effects of functional food ingredients on these parameters. SSE supplementation for 12 weeks did not have any severe adverse health effects. In addition, we showed that high-dose SSE supplementation (210 mg/day as serotonin derivative aglycons) for four weeks did not have severe adverse effects.³³ These findings suggest that SSE may be safe for daily use as a dietary supplement over a long time period. In conclusion, this study suggests that SSE ameliorates arterial stiffness and therefore may have the potential to decrease cardiovascular risk.

Vascular Health and Risk Management

Publish your work in this journal

Vascular Health and Risk Management is an international, peer-reviewed journal of therapeutics and risk management, focusing on concise rapid reporting of clinical studies on the processes involved in the maintenance of vascular health; the monitoring, prevention and treatment of vascular disease and its sequelae; and the involvement of

metabolic disorders, particularly diabetes. This journal is indexed on PubMed Central and MedLine. The manuscript management system is completely online and includes a very quick and fair peer-review system, which is all easy to use. Visit <http://www.dovepress.com/testimonials.php> to read real quotes from published authors.

Submit your manuscript here: <http://www.dovepress.com/vascular-health-and-risk-management-journal>
