Background: Previous studies have reported that patients with stroke have a high incidence of cognitive decline. The aim was to elucidate the association between serum E-selectin levels and cognitive function in stroke patients.

Materials and Methods: Serum levels of E-selectin were measured in 322 patients with stroke at baseline. Cox proportional hazard analysis was used to evaluate the predictive value of serum E-selectin for predicting cognitive decline (end point) in patients with stroke.

Results: Multivariate linear regression analysis revealed that serum E-selectin levels were independently associated with MOCA score after adjusting for age, gender, BMI, current smoker, current drinker, admission systolic and diastolic BP, CVD history and laboratory measurements in patients with stroke at baseline ($S\beta = -0.156$; 95% CI, -0.170– -0.074; $P < 0.001$). The multivariate Cox proportional hazard analysis revealed that serum E-selectin ($HR = 2.481$, 95% CI 1.533–4.327, P -trend < 0.001) was an independent prognostic factor for cognitive decline in these patients with stroke during the follow-up period.

Conclusion: Our results showed that increased serum E-selectin levels were significantly and independently associated with cognitive decline and had independent predictive value for cognitive decline in patients with stroke. Serum E-selectin might enable early recognition of cognitive decline among stroke patients.

Keywords: E-selectin, stroke cognitive decline, prognostic value

Introduction

People with stroke among older population have been strongly associated with an increased risk of developing cognitive decline.^{1–4} Existing studies suggested that cognitive impairment was higher in people with stroke than in those without stroke.⁵ Although the current mechanisms are poorly understood, increasing inflammation and oxidative stress in stroke play important impacts on an increased risk for cognitive impairment.^{6,7} Cognitive decline is a major health problem among older population and has been identified as the strongest independent predictor of heavy medical burden and poor quality of life. Hence, identifying relevant risk factors of cognitive decline in patients with stroke has to be addressed.

The inflammatory responses are a common feature of cardiovascular diseases (CVDs).^{8–10} Inflammatory mediators including interleukin (IL), chemokines and tumor necrosis factor- α (TNF- α) play an important role in the occurrence and progress of CVDs. E-selectin is an adhesion molecule and is expressed on vascular endothelial cells. Like other pro-inflammatory cytokines, such as TNF- α or IL-1 β , E-selectin is involved in various inflammatory reactions.²⁰ Existing evidence suggested that E-selectin, as a new inflammatory cytokine,^{11–13} is involved in the

progress of CVDs.^{14–16} As a chronic inflammatory disease, stroke can hasten the progression of cognitive decline and contribute to a higher rate of cognitive decline.^{4–6} Hence, given the close association between E-selectin and inflammation,^{11–14} we hypothesized that serum E-selectin levels might be associated with cognitive decline in stroke patients.

To date, few study has explored the association between serum E-selectin levels and cognitive decline in patients with stroke. We aimed to investigate whether increased E-selectin levels were associated with elevated risk of cognitive decline in patients with stroke. This was also the first study to explore the prognostic value of E-selectin for predicting cognitive decline in stroke patients.

Materials and Methods

Study Population

We studied 322 hospitalized patients from the first hospital of Hebei Medical University in China because of ischemic or hemorrhagic stroke between January 2014 and August 2016. All stroke patients did not had other serious acute illnesses and were stable for more than three months before admission. Patients with stroke were clinically stable during hospitalization and were prospectively followed up after discharge. The diagnosis of stroke was performed by two neurologists who used the same diagnostic criteria for these stroke patients.¹⁷ Montreal cognitive assessment (MOCA) was used for the assessment of mild cognitive impairment (MCI) and is a rapid screening assessment tool of cognitive function.¹⁸ The cognitive areas of assessments include concentration and attention, memory, executive function, visual structure skills, language, calculation, abstract thinking and orientation. The total score of the scale is 30 points, and patients with value <26 points were considered as MCI. For the purposes of this study, MCI was considered cognitive decline. Of these patients, 68 patients with stroke were identified as cognitive decline (MCI) in this study. Patients with liver and kidney dysfunction, respiratory diseases, neoplastic diseases, or other serious diseases were excluded (N=12).

The diagnosis of other CVDs, including coronary heart disease, hypertension and others was based on the patient's current or previous medical records. Other data on clinical characteristics, including age, gender, body

mass index (BMI), smoking, alcohol consumption, blood pressure (BP) and others were collected from patient interviews or medical records. According to the Declaration of Helsinki guidelines, the Ethics Committee of the first hospital of Hebei Medical University approved this study, and all patients gave written informed consent.

Follow-Up

All patients after discharge were followed up for a mean of 34 ± 5 months prospectively. Patients were followed up by telephone or review of the medical record four times a year until the occurrence of MCI.

Measurement of E-Selectin Levels

Fasting venous blood samples from patients with stroke were collected within the first 24 hours after admission. The samples were prepared immediately by centrifugation and processed for determination of E-selectin levels. Serum levels of E-selectin were measured by electrochemiluminescence immunoassay (Cobas e 601, F. Hoffmann-La Roche Ltd.). E-selectin levels were measured three times, and the average of the three times was used for the final analysis (coefficient of variation of precision [CV], <5%).

Laboratory Measurements

Fasting venous blood samples from patients with stroke were also tested for albumin (ALB), blood glucose (FBG), hemoglobin (Hb), fasting, hs-CRP (hs-C-reactive protein), HbA1c (glycosylated hemoglobin), high-density lipoprotein (HDL) and LDL (low-density lipoprotein) with the use of the Siemens ADVIA 2400 automatic biochemistry analyzer (Siemens AG). Estimated glomerular filtration rate (eGFR) was calculated by the Modification of Diet in Renal Disease (MDRD) formula.¹⁹

Statistical Analyses

The Kolmogorov–Smirnov test was used to analyze the normality of the data. P value ≤ 0.05 was considered to be statistically significant. The data that were not normally distributed were analyzed by the Mann–Whitney U -test and then were expressed as the median (interquartile range [IQR]). Data were analyzed by independent t -test and presented as the mean \pm SD for normally distributed data. The chi-square test was used to analyze analyzed categorical variables and was expressed as n (%).

Multivariate linear regression model was used to assess the independent relationship between serum E-selectin levels and MOCA score in stroke patients at baseline. Then, the Cox proportional hazard analysis was performed to assess the independent prognostic factors for cognitive decline (MCI) in patients with stroke during the follow-up period. In these Multivariate analyses, we adjusted for clinical data relevant to stroke and cognitive function even if the factors were not significantly associated with cognitive decline in the univariate analysis because they are key clinical variables and may be associated with cognitive decline in the multivariate but not univariate analyses. Additionally, sensitivity and stratification analyses were also performed to evaluate the independent association between serum E-selectin levels and cognitive decline by, respectively, adding “cognitive therapy” and “CVD history” as covariates. All of the analyses were performed by using SPSS 23.0.

Results

Clinical Characteristics of Study Subjects at Baseline

To evaluate serum E-selectin levels in stroke patients, 358 age-and gender-matched healthy subjects, who have undergone physical examination without stroke and any other severe illnesses, were obtained as the control group. Our results suggested that serum levels of E-selectin were significantly higher than healthy subjects (Table 1). The clinical characteristics at baseline of stroke patients are presented in Table 2. The age of all included patients was 65.3±5.7 years and males were 151 (46.89%). MOCA score was 25.8±4.6 in all stroke patients.

Table 1 Baseline Characteristics of Patients with Stroke and Healthy Subjects

Variables	Healthy Subjects (n=358)	Patients with Stroke (n=322)	P value
Age (years)	64.6±5.9	65.3±5.7	0.485
Gender (male), n (%)	174 (48.6)	151 (46.89)	0.159
Serum soluble E-selectin (ng/mL)	31.39±4.82	77.38±8.62	<0.001

Note: Data are presented as mean ± SD for normally distributed data, as median (interquartile range) for nonnormally distributed data, and as n (%) for categorical variables.

Table 2 Clinical Characteristics in 322 Patients with Stroke at Baseline

Variables	All Patients with Stroke (n=322)
Age (years)	65.3±5.7
Gender (male), n (%)	151 (46.89)
BMI (kg/m ²)	26.3 (24.3–27.5)
Current smoker, n (%)	64 (19.9)
Current drinker, n (%)	322 (26.4)
Admission systolic BP (mmHg)	139.6 (129.2–157.3)
Admission diastolic BP (mmHg)	82.3 (80.4–93.4)

Increased Serum Levels of E-Selectin Showed a Significant Association with MOCA Score in 322 Patients with Stroke

To assess the association of serum E-selectin levels in stroke patients with MOCA score, multivariate linear regression model was performed (Table 3). Model 1 showed that higher serum levels of E-selectin were significantly associated with MOCA score after no adjustment was made ($S\beta = -0.182$, 95% CI $-0.226 - -0.101$, $P < 0.001$). The results of Model 2 were similar to those of Model 1 ($S\beta = -0.169$, 95% CI $-0.198 - -0.092$, $P < 0.001$), after adjustments were made for age, gender, BMI, current smoker, current drinker, admission systolic and diastolic BP and CVD history. This

Table 3 Multivariate Linear Regression Analysis for the Association Between the Serum Soluble E-Selectin Levels and MOCA Score in 322 Patients with Stroke at Baseline

Variables	R ²	Sβ	95% CI	P value
Serum soluble E-selectin (ng/mL) (per 1-SD increase)				
Model 1	0.042	-0.182	- 0.226-- - 0.101	<0.001
Model 2	0.178	-0.169	- 0.198-- - 0.092	<0.001
Model 3	0.253	-0.156	- 0.170-- - 0.074	<0.001

Notes: Model 1: No adjustment. Model 2: Adjusted for age, gender, BMI, current smoker, current drinker, admission systolic and diastolic BP and CVD history. Model 3: Adjusted for age, gender, BMI, current smoker, current drinker, admission systolic and diastolic BP, CVD history and laboratory measurements.

Abbreviations: MOCA, montreal cognitive assessment; BMI, body mass index; BP, blood pressure; CVD, cardiovascular disease.

relationship in Model 3 remained statistically significant and changed minimally after adding laboratory measurements to Model 2 (Sβ= -0.156, 95% CI -0.170 - -0.074, P<0.001).

Cox Proportional Hazard Analysis for Predicting Cognitive Decline (MCI) in 322 Stroke Patients

All included stroke patients (N=322) were prospectively followed up for a mean of 34 ±5 months. Sixty-eight of the included stroke patients have cognitive decline (MCI). To assess the risk factors for cognitive decline, multivariate Cox proportional hazard regression model was performed (Table 4). Multivariate Cox proportional hazard analysis suggested that serum levels of E-selectin (HR=2.481, 95% CI 1.533–4.327, P-trend<0.001, Model 3) were an independent prognostic factor for cognitive decline after adjustments of age, gender, BMI, current smoker, current drinker, admission systolic and diastolic BP, CVD history

and laboratory measurements were made. Kaplan-Meier analysis showed that stroke patients with serum levels of E-selectin above the mean had a significantly higher rate of cognitive decline than patients with serum levels of E-selectin below the mean value (data not shown).

Sensitivity and Stratification Analysis for Predicting Cognitive Decline (MCI) in 322 Stroke Patients

We performed an additional sensitivity analysis to evaluate the association of serum E-selectin with cognitive decline in stroke patients by adding “cognitive therapy” as a covariate (Table 5). The sensitivity analysis suggested that higher serum E-selectin levels were still independently associated with a higher risk of cognitive decline during the follow-up. Stratified analysis, by adding “CVD history” as a covariate, showed that the significant association between serum E-selectin levels and cognitive decline (MCI) in stroke patients was affected by CVD history. A significant association exists in patient with CVD history but not in patient without CVD history (Table 6).

Discussion

In this study, our results suggested that serum E-selectin levels had independent good predictive value for cognitive decline (MCI) in patients with stroke by multivariate Cox proportional hazard analysis.

E-selectin is an adhesion molecule and is expressed on vascular endothelial cells. Like other pro-inflammatory cytokines, E-selectin is involved in various inflammatory reactions.²⁰ E-selectin is a mediator of leukocyte rolling and recruitment during infection. E-selectin plays an important role in the attachment of leukocytes to endothelial cells and the accumulation of leukocytes in inflamed tissues during infectious diseases, malignant tumors, and

autoimmune diseases.^{20–22} Recently, E-selectin is also involved in the development of chronic vascular inflammation,^{23–27} which has been considered as an important role in promoting atherosclerosis-related diseases such as stroke and coronary heart disease.^{28–31} Therefore, based on existing evidence, it can be hypothesized that E-selectin plays an important role in cognitive decline (MCI) by stroke.

In the current study, we first showed that higher serum levels of E-selectin had an increased MOCA score at baseline and then had higher risk of cognitive decline after a follow-up of 3 years, which may be mostly or partly explained by the research about inflammatory mechanism performed in previous studies.^{28–30} These studies have suggested that chronic vascular inflammation caused by stroke promotes events of cognitive decline.^{23–31} The increased serum levels of E-selectin may be the result of the aggravation of inflammation in stroke patients, which suggested that higher serum E-selectin levels were associated with an increased risk rate of cognitive decline in stroke patients. The mechanism of chronic inflammation seems to be a better explanation of the

association between E-selectin and cognitive decline, which is consistent with our results. Additionally, we performed an additional sensitivity analysis to evaluate the association of serum E-selectin with cognitive decline in stroke patients by adding “cognitive therapy” as a covariate. The results suggested that higher serum E-selectin levels were still independently associated with a higher risk of cognitive decline during the follow-up of 3 years. Therefore, the early detection of cognitive decline in these stroke patients may provide us a change to develop strategies aiming to reduce the medical burden and improve prognosis. Our results seemed to imply that serum E-selectin might be a sensitive biomarker for the early recognition of cognitive decline in patients with stroke.

Our results have several obvious strengths. First, we are first to found that serum E-selectin can be considered as a valuable prognostic factor for cognitive decline in stroke patients. Second, we ensured comprehensive follow-up and rigorous adjudication of cognitive decline (MCI) and so our results are very reliable. Third, the serum E-selectin assay chosen for this study is both widely available and

analytically stable (coefficient of variation of precision <5%). This serum index is convenient and reliable for clinical popularization. Certainly, this study also has several limitations. The study size was single-center with fairly small samples. Then, E-selectin was only measured once in the morning of the first day after admission. The time courses of E-selectin levels were not evaluated. Information regarding the long-term prognosis throughout the hospitalization period was not available. Further investigation will be necessary to solidify the clinical significance of E-selectin on predicting cognitive decline in patients with stroke by evaluating the time course of E-selectin.

Conclusions

We demonstrated that serum E-selectin is an independent prognostic factor for cognitive decline in patients with stroke. These results suggest that E-selectin might be a useful biomarker for predicting cognitive decline of patients with stroke.
