Background: Glioma is a common intracranial malignant tumor with high rates of invasiveness and mortality. This study aimed to investigate the mechanism of rapamycin in glioma.

Methods: U118-MG cells were treated with and without rapamycin in vivo and then collected for RNA sequencing. Differentially expressed miRNAs (DEMs) were screened and verified. MiR-26a-5p was selected for functional verification, and the target gene of miR-26a-5p was identified. The effects of miR-26a-5p on cell proliferation, cell cycle, apoptosis, and autophagy were also investigated.

Results: In total, 58 up-regulated and 41 down-regulated DEMs were identified between rapamycin-treated and untreated U118-MG cells. MiR-26-5p levels were up-regulated in U118-MG cells treated with 12.5 μ M rapamycin, and death-associated protein kinase 1 (DAPK1) expression, a direct miR-26a-5p target gene, was down-regulated. Rapamycin substantially inhibited cell proliferation and cell percentage in the S phase and promoted cell apoptosis; miR-26a-5p inhibitor increased cell proliferation and cell cycle and decreased cell apoptosis; DAPK1 overexpression further induced cell proliferation, increased the cell number in the S phase, and inhibited apoptosis in glioma cells. Notably, rapamycin increased the autophagy-related Beclin1 protein expression levels and the LC3 II/I ratio.

Conclusion: Rapamycin exerts anti-tumor effects by promoting autophagy in glioma cells, which was dependent on the miR-26a-5p/DAPK1 pathway activation by rapamycin.

Keywords: rapamycin, autophagy, RNA sequencing, glioma cells, miR-26a-5p, death-associated protein kinase 1

Introduction

As a common intracranial malignant tumor, glioma, caused by the carcinogenesis of glial cells originating in the neuroectoderm, has a high mortality.¹ Early diagnosis and effective treatment are effective approaches to prevent further glioma deterioration.² Recent studies have reported intensive progress in glioma treatment, including immunotherapy, sophisticated surgical resection and advanced chemoradiation.^{2,3} However, due to complex pathogenesis and higher recurrence, unsatisfactory prognosis and poor survival still exist.² Therefore, it is essential to identify novel diagnostic and prognostic biomarkers and therapeutic targets, and to further elucidate the underlying molecular mechanisms of glioma.

The DAPK family contains five kinases, namely DAPK1, DAPK 2, ZIPK, DRAK1, and DRAK2, among which DAPK1 is a Ca²⁺/CaM-dependent Ser/Thr protein kinase.⁴ In 1995, Deiss et al discovered the DAPK1 gene through functional gene cloning technology when Hela cell death was induced with interferon- γ .⁵ This

gene, located at chromosome 9q34.1, with a protein molecular weight of 160 kD, participates in many pathologic and physiologic processes including cell necrosis, apoptosis, and autophagy and is related to the biological activity of tumors.⁶⁻⁸

It is well-known that the continuous updating of high-throughput sequencing and computer algorithms has revealed a large number of non-coding RNAs involved in various biological functions, including cell differentiation, apoptosis, migration, invasion, and proliferation in human diseases.⁹ MicroRNAs (miRNAs) are endogenous non-coding small-molecule RNAs that widely exist in several conditions.¹⁰ A growing number of studies have focused on and explored the functions of miRNAs in cancers.¹¹ Previous studies have reported the abnormal expression of miRNAs in glioma and identified several miRNAs, including miRNA-204-5p,¹² miRNA-637,¹³ miRNA-155,¹⁴ and miRNA-485-5p as diagnostic and prognostic biomarkers.¹⁵

Rapamycin, also known as sirolimus, is a common inhibitor of mammalian target of rapamycin (mTOR).¹⁶ Hyperactivation of mTOR kinase usually occurs in various cancers and plays a critical role in cell growth, proliferation, autophagy and metabolism.¹⁷ Previous studies have demonstrated the tumor-inhibiting effect of rapamycin on glioma/glioblastoma.¹⁸⁻²² Rapamycin induces glioma stem/progenitor cell differentiation by activating autophagy.²³ Yang et al showed suppressed growth and proliferation of human U87MG glioma cells by rapamycin combined with nimuatine, with cells arrested in the G1 phase.²⁴ Moreover, rapamycin has been shown to promote autophagy and Beclin1 gene expression, increase the LC3 II/I ratio, and decrease P62 gene expression.²⁵

This study determined the effects of rapamycin on the proliferation, cell cycle, apoptosis, and autophagy of glioma cells, and whether the inhibitory effect of rapamycin on glioma cell growth may be related to the miR-26a-5p/DAPK1 pathway, which provides evidence for future studies of the mechanisms of action of rapamycin.

Materials and Methods

Cell Culture

Four glioma cell lines (U87, U118-MG, U251 and A172) were obtained from Shanghai Obio Technology Co., Ltd., and then maintained in complete DMEM medium (Hyclone) at 37 °C and 5% CO₂.

CCK8 Assay

U87, U118-MG, U251, and A172 cells (5×10^3 /each well) were grown in 96-well plates, respectively, and then exposed to rapamycin (Sigma) at different concentrations (0, 12.5, 50, 100, 150, 200, and 250 μM) for 12, 24, 48, and 72 h followed by the addition of 100 μL of CCK8 (Biosharp) for 1 h. Microplate spectrophotometer was used to evaluate cell viability based on the absorbance at 450 nm.

Western Blotting

U118-MG cells were exposed to 10 and 100 μM rapamycin for 0, 0.5, 1, 2, 4, 6, 12, 24, 48, and 72 h.

Cells were then lysed by RIPA lysis buffer (Gibco), and proteins extracted using commercial kit (Pierce, Rockford, IL, USA). After being resolved via SDS PAGE, protein samples were transferred to a PVDF membrane, which was blocked and reacted with DAPK1, LC3, Beclin1, or β-actin primary antibody (1:800, Abcam) overnight at 4 °C. After incubation with secondary antibody (1:5000, Abcam), protein levels were detected via enhanced chemiluminescence (Millipore, USA).

RNA Extraction and Sequencing

U118-MG cells were treated with 12.5 μM of rapamycin for 48 h. Cells were then collected, and total RNA isolated using RNAiso Plus (Takara, Shiga, Japan). RNA detection was carried out using a spectrophotometer (NanoDrop Technologies, Wilmington, Delaware, USA), and RNA with $2.0 < A260/A280 < 2.2$ was used for subsequent RNA sequencing. Subsequently, TruSeq[®] Small RNA Library Prep Kit for Illumina[®] (New England Biolabs Inc., Beverly, MA, USA) was used to construct the RNA-seq library, with the Illumina Hiseq 2500 platform (Illumina, San Diego, CA, USA) used for sequencing.

Data Analysis

Data preprocessing was performed use the Oligo package (version 1.36.1, <http://bioconductor.org/packages/release/bioc/html/oligo.html>) of R software, which mainly consisted of background correction, normalization and expression calculation. The classical Bayes method provided by the Limma package was employed to screen DEMs between control cells and cells treated with rapamycin. The p-value was estimated with the adjusted p-value (adj.p.value) was then determined based on the Benjamini & Hochberg method. Notably, the DEMs in

this study were defined according to the cutoffs of $p < 0.05$ and $|\log \text{ fold change (FC)}| > 0.5$. Meanwhile, a Venn diagram was generated based on the obtained DEMs.

qRT-PCR Analysis

Total RNA was obtained using Trizol (Invitrogen) following the manufacturer's instructions. ReverAid First Strand cDNA Synthesis Kit (Invitrogen) was used to obtain cDNA by RNA reverse transcription. qRT-PCR was carried out using SYBR Green qPCR Master Mix (Roche). PCR primers were: miR-143 sense primer 5'-GGG GTG AGA TGA AGC ACT GTA GCT C-3' and antisense primer 5'-GGG GTA AGG CAC GCG GTG AAT GCC AA-3'; miR-26a-5p sense primer 5'-GGG GTT CAA GTA ATC CAG GA-3' and antisense primer 5'-TGC GTG TCG TGG AGT C-3'; and U6 sense primer 5'-CTC ACT TCG GCA GCA CAT A-3' and antisense primer 5'-AAC TCT TCA CGA TTT TGT CTG TC-3'; U6 served as the internal control. Finally, miRNA expression data was evaluated by the $2^{-\Delta\Delta Ct}$ method.

Luciferase Reporter Assay

Dual-luciferase activity assays were used to identify the targeted relationship between miR-26a-5p and DAPK1. The DAPK1 3'-UTR-wild-type (WT) or mutant (MUT) were cloned into a pGL3 vector, and named DAPK1-WT, and DAPK1-MUT, respectively. MiR-26a-5p mimic or mimic control was co-transfected with DAPK1-WT or DAPK1-MUT into 293T cells, respectively, for 48 h using Lipofectamine 2000. Luciferase activity measurements were carried out using the Dual-Glo Luciferase Assay System (Promega).

Cell Transient Transfection and Treatment

MiR-26a-5p inhibitor, inhibitor NC, DAPK1 overexpression vector (pc-DAPK1), and pcDNA3.1 were provided by Jirui Technology CO., Ltd. (Shanghai, China). To evaluate the effect of miR-26a-5p on rapamycin-treated U118-MG cells, U118-MG cells were grown in 6-well plates for 24 h, and then transiently transfected with the above vectors using Lipofectamine 3000 (Thermo). Following 24 h of transfection, cells were treated with 12.5 μM rapamycin for 48 h.

Ethynyldeoxyuridine (EdU) Assay

The EdU kit (Invitrogen) was used for cell proliferation detection. Specifically, transfected U118-MG cells were

incubated with 12.5 μM rapamycin and 10 μM EdU for 48 h, followed by cell collection and rinsing with PBS. Following treatment with 4% paraformaldehyde to fix cells for 15 min away from light, cells were incubated with working solution for 30 min. A flow cytometer (BD, CA, USA) was used to calculate the percentage of EdU-positive cells.

Flow Cytometry Assay

Cell cycle and apoptosis were evaluated by flow cytometry. Cells from various treatments were digested with trypsin and harvested. For cell cycle assays, cells were incubated on ice in 70% ethanol for 2 h and then stained with propidium iodide (PI) for 30 min at 37 °C in the dark. Apoptosis was detected according to instructions of the FITC-Annexin V Apoptosis kit (BD, CA, USA). A flow cytometer (BD, CA, USA) was used to measure the cell cycle and calculate the apoptotic cells numbers.

Statistical Analysis

Values are expressed as mean \pm SD from three independent experiments. And the SPSS software was used for one-way analysis of variance followed by multiple comparisons, and $p < 0.05$ and $P < 0.01$ were considered the threshold for significant difference and very significant difference, respectively.

Results

Effect of Rapamycin on Different Glioma Cell

Four glioma cells (U87, U118-MG, U251, and A172 cells) were exposed to different rapamycin concentrations. CCK8 assay showed that rapamycin inhibited the cell viability of U118-MG and U87 cells at 24, 48 and 72 hours, and at 48 and 72 hours, respectively, (Figure 1A). A172 and U251 cell viability was not dose-dependent upon rapamycin treatment (Supplementary Figure S1A). U87 and U118-MG cell treatment with different concentrations of rapamycin (10 and 100 μM), respectively, and Western blotting showed that rapamycin treatment decreased DAPK1 and P62 expression, and elevated the LC3 II/I ratio in U118-MG and U87 cells (Supplementary Figure S1B). Furthermore, for U118-MG cells treated with increased rapamycin concentration for 72 h, results showed that 150–250 μM rapamycin treatment caused massive cell death, with P62 expression was obviously reduced after treatment with 12.5 μM rapamycin (Figure 1B). The 12.5 μM rapamycin concentration was

DAPK1 Was Verified as a Functional Target of miR-26a-5p

DAPK1 was considered a potential target gene of miR-26a-5p according to TargetScan databases (Figure 3A). Luciferase reporter assay showed that after co-transfection with DAPK1-WT and miR-26a-5p mimic, the luciferase activity was reduced compared to co-transfection with mimic control, where no significant difference was found after DAPK1-MUT treatment (Figure 3B), suggesting that DAPK1 is a direct miR-26a-5p target gene.

Effect of Rapamycin on Cell Proliferation, Cell Cycle and Apoptosis in Glioma Cells

The Edu assay showed that rapamycin significantly inhibited cell proliferation, and the addition of a miR26a inhibitor increased cell proliferation, whereas the addition of pc-DAPK1 significantly promoted cell proliferation (Figure 4A). Cell cycle analysis results showed that rapamycin significantly inhibited the number of S phase cells, whereas the addition of pc-DAPK1 significantly increased the number of S phase cells (Figure 4B). Additionally, rapamycin treatment promoted apoptosis, while the addition of miR-26a-5p inhibitor inhibited apoptosis, and the overexpression of DAPK1 further decreased the number of apoptotic cells (Figure 4C).

Effect of Rapamycin on Cell Autophagy in Glioma Cells

When U118-MG cells were treated with rapamycin, miR-26a-5p inhibitor and/or pc-DAPK1 for 48 h, RT-qPCR showed that miR-26a-5p levels were significantly increased after treatment with rapamycin, whereas miR-26a-5p levels were significantly inhibited by the miR-26a-5p inhibitor (Figure 5A). However, DAPK1 mRNA expression levels decreased significantly after rapamycin treatment, increasing significantly with the addition of miR-26a-5p inhibitor and pc-DAPK1 (Figure 5B). Additionally, Western blotting showed that after treatment with rapamycin, DAPK1 protein expression levels decreased significantly, whereas Beclin1 protein expression levels and LC3 II/I ratio increased significantly (Figure 5C). Additionally, to further verify that rapamycin can promote glioma cell autophagy, an immunofluorescence assay was used to detect LC3 expression. Results showed that rapamycin promoted glioma cell autophagy through the miR-26a-5p/DAPK1 signaling pathway (Figure 5D).

Discussion

Glioma is a primary brain tumor that seriously affects human health. DAPK1 has been confirmed to be related to glioma cell activity, meaning DAPK1 may be a target for glioma therapy. DAPK1, calcium/calmodulin-regulated serine/threonine kinase, plays key roles in mediating cell

apoptosis and autophagy.²⁶ Autophagy is a lysosomal-mediated process involved in cell growth, differentiation, viability and other pathological and physiological processes.²⁷ It degrades damaged intracellular organelles, abnormal protein and other substances deposition, and maintains cellular homeostasis.²⁸ Therefore, autophagy is

a conservative in vivo system that plays a dual role in tumor occurrence and development.²⁹

Few studies have focused on the illuminating mechanism of action of rapamycin in glioma cell via bioinformatics analyses. Additionally, accumulating evidence has indicated a generally low miR-26a-5p expression in

several cancers, including bladder cancer,³⁰ colorectal carcinoma,³¹ prostate cancer,³² and lung cancer,³³ whereas high miR-26a-5p expression levels can inhibit tumor growth. In the present study, we found that 58 DEMs were up-regulated and 41 DEMs were down-regulated in rapamycin-treated U118-MG cells based on bioinformatics

analysis. MiR-26-5p was proved to be highly expressed in U118-MG cells treated with 12.5 μ M rapamycin. Additionally, studies have shown that rapamycin can inhibit cell proliferation, arrest the cell cycle in the G1 phase, and promote apoptosis.^{20–22} In this study, rapamycin inhibited cell proliferation and the number of cells in S phase

and promoted apoptosis; the addition of miR-26a-5p inhibitor reduced the rapamycin effect on inhibiting cell proliferation, stagnated the cell cycle in S phase, promoting apoptosis, and increased Beclin1 protein expression levels and LC3 II/I ratio. Therefore, rapamycin may inhibit glioma cell growth by up-regulating miR-26a-5p expression.

Studies have confirmed that Beclin1 and LC3 II/I ratio are indices of autophagy activity.³⁴ This study demonstrated that rapamycin could regulate Beclin1 and LC3 expression. Generally, more than 30 autophagy-related (ATG) genes are involved in every step of this process.³⁴ Among them, microtubule associated protein1 light chain 3, a mammalian homolog of yeast Atg8, is considered a key regulator of autophagy, participating in several steps, including the growth of autophagic membranes, recognition of autophagic cargoes, and fusion of autophagosomes with lysosomes.^{35–37} LC3 is synthesized as a precursor form cleaved by the protease ATG4B, resulting in the cytosolic isoform LC3-I. In turn, LC3-I is conjugated to phosphatidylethanolamine to form LC3-II upon autophagy induction.^{38–40} LC3-II binds to the autophagosome membrane and remains bound to it until it is degraded in the autolysosomes. LC3-II is an important marker for assessing autophagy activity and is the only reliable autophagy marker to date.⁴¹ Therefore, in this study, LC3 protein expression was detected via immunofluorescence. Results showed that rapamycin increased LC3 expression, which further revealed that rapamycin could promote autophagy.

Furthermore, DAPK1 was confirmed as the direct target gene of miR-26a-5p. MiR-26a-5p could reduce DAPK1 expression, which could be attenuated by the addition of the miR-26a-5p inhibitor. Furthermore, rapamycin could up-regulate miR-26a-5p expression. Notably, rapamycin could also reduce DAPK1 expression and promote autophagy-related protein expression. Rapamycin treatment increased Beclin1 and LC3 II/I expression levels.

Conclusions

In this study, we found that miR-26a-5p was overexpressed in rapamycin-treated glioma cells, whereas DAPK1 expression was inhibited. Additionally, rapamycin may exert its antitumor effect by promoting autophagy depending on miR-26a-5p/DAPK1 pathway activation by rapamycin.

Cancer Management and Research

Dovepress

Publish your work in this journal

Cancer Management and Research is an international, peer-reviewed open access journal focusing on cancer research and the optimal use of preventative and integrated treatment interventions to achieve improved outcomes, enhanced survival and quality of life for the cancer patient.

The manuscript management system is completely online and includes a very quick and fair peer-review system, which is all easy to use. Visit <http://www.dovepress.com/testimonials.php> to read real quotes from published authors.

Submit your manuscript here: <https://www.dovepress.com/cancer-management-and-research-journal>
