Abstract: The rising outbreak of SARS-CoV-2 continues to unfold all over the world. The development of novel effective antiviral drugs to fight against SARS-CoV-2 is a time cost. As a result, some specific FDA-approved drugs have already been repurposed and authorized for COVID-19 treatment. The repurposed drugs used were either antiviral or non-antiviral drugs. Accordingly, the present review thoroughly focuses on the repurposing efficacy of these drugs including clinical trials experienced, the combination therapies used, the novel methods followed for treatment, and their future perspective. Therefore, drug repurposing was regarded as an effective avenue for COVID-19 treatment. Recently, molnupiravir is a prodrug antiviral medication that was approved in the United Kingdom in November 2021 for the treatment of COVID-19. On the other hand, PF-07321332 is an oral antiviral drug developed by Pfizer. For the treatment of COVID-19, the PF-07321332/ritonavir combination medication is used in Phase III studies and was marketed as Paxlovid. Herein, we represented the almost history of combating COVID-19 from repurposing to the recently available oral anti-SARS-CoV-2 candidates, as a new hope to end the current pandemic.

Keywords: SARS-CoV-2, drug repurposing, clinical trials, molnupiravir, paxlovid

Introduction

The human respiratory system is targeted by coronaviruses (CoV). Coronaviruses are responsible for these dangerous outbreaks, such as the Middle East Respiratory Syndrome (MERS-CoVs), Severe Acute Respiratory Syndrome (SARS-CoV),¹ and finally, the novel Severe Acute Respiratory Syndrome (SARS-CoV-2) causing COVID-19 disease.²⁻⁶ COVID-19 was nominated for the identification of the SARS-CoV-2 in Wuhan city (China) by December 2019.^{1,2,7-10} Thus, the World Health Organization (WHO) guided to do some tests about the recent emergence of this outbreak, infection control, and its abolishment.^{10,11} The first appearance of COVID-19 was through an unknown source of an animal at a seafood market and that was responsible for the emerged outbreak.¹⁰ However, it was enrolled that the main source of contagion was from animals (zoonotic)¹² including intermediate hosts like a bat.⁸ Hence, SARS-CoV-2 is a positive single-RNA stranded virus that may provoke diseases in humans or animals. There are 4 -CoV subfamilies (gamma, delta, alpha, and beta -CoV), but SARS-CoV-2 belongs to the beta-CoV subfamily. Although mammals are affected by beta and alpha -CoV viruses, however birds are affected by delta and gamma -CoV viruses.^{6,13,14}

The studies on SARS-CoV-2 propose that most cases may be started by comparatively low loads of virus with syndromes starting from asymptomatic to mild/moderate diseases having different durations.¹⁵ Common typical symptoms like cough and fever are the beginning of the appearance of a more serious virus that has a higher load.^{1,12} As the

Graphical Abstract

disease proceeds, some symptoms may appear, such as hypoxemia, fever, pneumonia, and inflammatory responses. Hence, the patient should go to the hospital.^{3,15} The majority of COVID-19 cases are either asymptomatic or experience moderate disease only. However, most cases that have a respiratory illness are usually required to go to hospitals.^{16,17}

COVID-19 has been an important overt issue all over the world since December (2019). The number of COVID-19 cases in territories and about 224 countries (Worldometer, 2021) has reached about 251,337,194 cases on the 9th of November 2021.¹⁸ The global breakthrough of this novel virus urges scientists all over the world to develop new vaccines and test them, ensuring their efficacy.^{19–22}

It is very important to point out the mutations experienced by SARS-CoV-2. Because extremely detrimental changes are swiftly purged, most mutations found in circulating SARS-CoV-2 virions' genomes are likely to be neutral or modestly deleterious.²³ This is because, while high-effect mutations that aid virus adaptation and fitness do occur, they are rare as compared to tolerable low-effect or no-effect “neutral” amino acid alterations. In at least certain settings, a tiny proportion of mutations are likely to affect virus phenotypic in a way that offers a fitness advantage. Pathogenicity, infectivity, transmissibility, and/or antigenicity of viruses may all be affected by such alterations.²³ In South Africa, a novel severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) variant B.1.1.529 was recently reported, causing a surge in COVID-19 cases.²⁴ The World Health Organization identified B.1.1.529, also known as Omicron, as a variant under monitoring (VUM) on November 24, 2021. The Omicron variation was identified as a variant of concern (VOC) two days later. This variation has a lot of mutations, including 15 alterations in the spike receptor-binding domain (RBD).²⁴

Drug repurposing – so-called therapeutic switching – is the new application of already existing therapeutics to another disease indication.^{25,26} The drug repurposing approach represents a rapid and low-cost drug discovery and development.²⁷ For example, recently repurposed drugs that were approved for treating coronary artery disease and erectile dysfunction were aspirin and sildenafil, respectively.²⁸

There are many claimed strategies introduced to combat SARS-CoV-2. An attractive one is to target ACE2 either directly through supplementation or indirectly through drugs that stimulate its downstream players.²⁹ In addition, the main protease (Mpro) is considered to be one of the main targets for drug development against SARS-CoV-2.⁵ Moreover, the anti-inflammatory strategies like nuclear factor erythroid 2 p45-related factor 2 (NRF2) activators can be deployed against the virus.³⁰

Based on the above, we can conclude the great importance of collecting and understanding the previously published articles regarding the efforts and trials for combating COVID-19. Herein, we reviewed most of the previously repurposed FDA-approved drugs, their clinical trials, and the newly introduced candidates to fight SARS-CoV-2. This may help scientists all over the world to make a broad scientific insight concerning this pandemic disease and the possible routes for its defeating.

SARS-CoV-2 Life Cycle and Its Potential Targets

Drugs target SARS-CoV-2 can be classified as (Figure 1):

1. Fusion inhibitors: inhibit the fusion process of viral entry
2. protease inhibitors: target some proteases,
3. Transcription inhibitors: target the reverse transcription step by blocking RNA-dependent RNA polymerase and preventing viral replication,
4. Some of the transcriptase inhibitors are nucleoside reverse transcriptase,
5. Some antivirals target M2 channel protein.

Human structure of covid 19 and its life cycle beside mechanism of action for some repurposing drugs :-

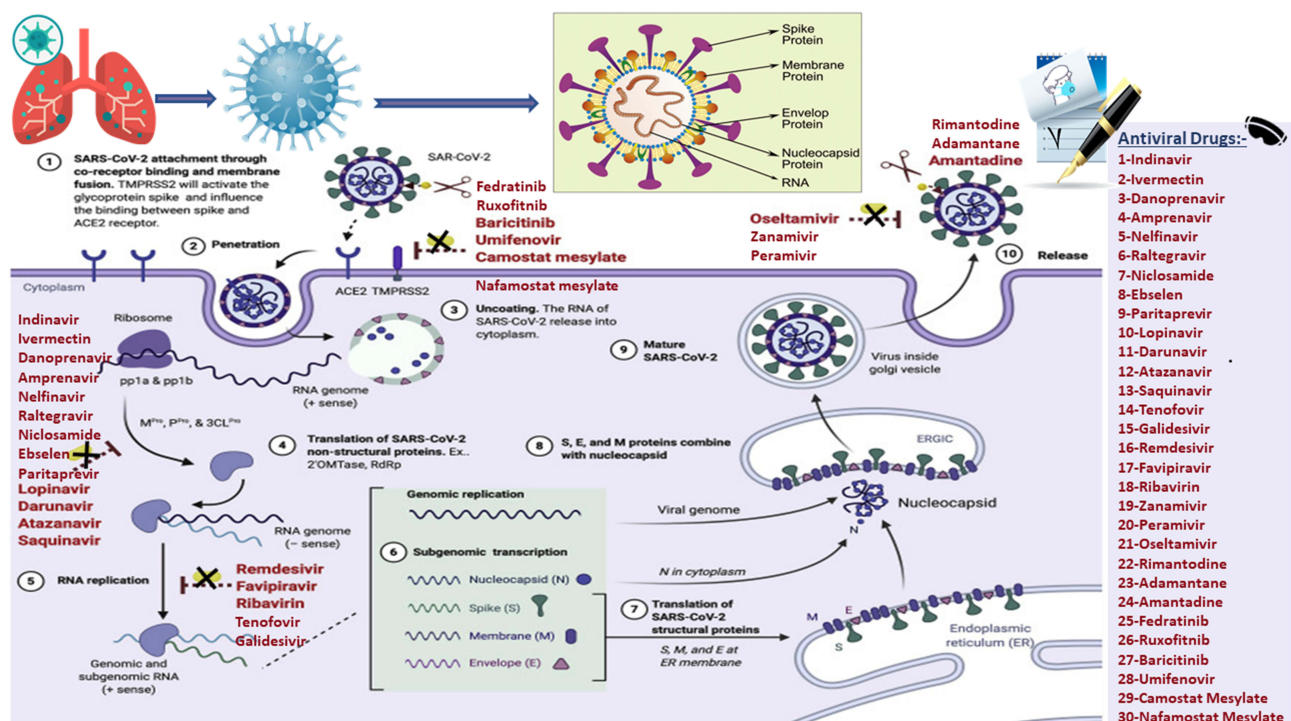

Figure 1 The life cycle of SARS-CoV-2, the potential targets of antiviral drugs, and their classification according to the mechanism of action.

Note: Created with BioRender.com.

The nucleocapsid (N) protein comprising the viral genome resides in the innermost layer of SARS-CoV-2. As described, SARS-CoV-2 is an RNA-positive-sense virus that helps it to translate its genome immediately upon entering the cell using host ribosomes. Thus, 29 distinct proteins are encoded in the genome.

The nucleocapsid contains the envelope (E) protein,³¹ and the entire envelope of the virus contains the membrane (M) protein. Besides, the spike (S) protein in the enveloped membrane on its surface is used by the virus when bound to host cells.³¹ Moreover, an angiotensin-converting enzyme-2 (ACE2) receptor is a protein that expresses itself in different types of cells, such as esophageal cells, absorbent enterocytes, myocardial cells, alveolar cells, and proximal cells of the kidneys.³² Thus, transmembrane serine protease 2 (TMPRSS2) is primed with the (S) protein, and SARS-CoV-2 infection in the cells of the lungs has been seen to be avoided by the TMPRSS2 inhibitor.

The cathepsin B/L – cysteine proteases – can promote the cleavage of (S) protein in TMPRSS2-negative cells³³ given the non-structural seven proteins are as follows: (ORF)7a, PLpro, Nsp12, Nsp3c, Mpro, Nsp1, and Nsp13. However, the four structural proteins are M, S, N, and E that is encoded by SARS-CoV-2.³⁴

The rationale behind the major components and biochemical events in the coronavirus replication cycle is considered as a crucial goal to develop new antiviral drugs. These include proteolytic enzymes and RNA-dependent RNA polymerases.³⁵ SARS-CoV-2 is transmitted in humans mainly by respiratory droplets, yet it might also go ahead in an airborne transition mode.³⁶ The virus comes into the steward cells during two pathways, either via plasma membrane fusibility or endosomes. Through both mechanisms, it engages ACE2 as an entry sensor and the viral S protein, which mediates binding to the host cell membrane.^{33,37}

A recent study showed that the attachment between S protein and ACE2 is activated by a host protease called TMPRSS2.³³ The virus uses S protein to neutralize antibodies, making it easier to bind to the host receptors.³⁸ Although the detailed fusion machinery of SARS-CoV-2 is not fully understood, the beta coronaviruses mostly use hemagglutinin-esterase (HE) to link to sialic acid on the glycoprotein surface. These fusion steps could be inhibited using fusion inhibitors. New insights into the antiviral effects of chloroquine against coronavirus what to expect for COVID-19?³⁹

After the fusion completion, the envelope is peeled off and the genome of SARS-CoV-2 along with its nucleocapsid penetrates the cytoplasm of the host cell.^{33,40} Its genome contains open reading frames 1a and 1b- (ORF1a and ORF1b) genes that produce two polyproteins (pp), pp1a and pp1b, that help in hijacking host ribosomes for the viral translation process.⁴¹

Then, papain-like protease (Ppro) and Mpro cleave these polyproteins to produce many non-structural proteins. Besides Ppro and Mpro, 3C-like cysteine protease (3CLPro) is suggested to exist in SARS-CoV-2 based on about 96% similarity with SARS-CoV by using a three-dimensional analysis model.⁴² These proteases play an extremely important role in viral transcription and replication. In addition, the design of protease inhibitors that inhibit these proteases are potential antivirals against SARS-CoV-2.⁴³

Since SARS-CoV-2 complete mechanisms have not been well understood yet, its replication explanation was based on MERS-CoV and SARS-CoV models because SARS-CoV-2 non-structural and structural proteins are similar to the proteins of these two kinds of viruses. A non-structural protein known as nsp12 forms a transcription and replication complex known as RNA-dependent RNA polymerases (RdRp).⁴⁴ Nsp12 is paired with its cofactor (nsp7 and nsp8) in SARS-CoV. This protein complex generates a negative-sense complementary RNA using the initial positive RNA as a reference.⁴⁵ The virus then uses the negative-strand RNA to synthesize new positive RNA molecules to process another stage of translation and replication and synthesize the genomes of the newest viral particles. In SARS-CoV, this process is regulated by topoisomerase III-beta. Using reverse transcription inhibitors, these stages can be disrupted by budding and assembly of the enveloped virus.⁴⁶ As post-translational alteration is necessary, the structural protein complexes (M, N, E, and S) form the sub-genomic RNA and then join the endoplasmic reticulum.⁴⁷ In the cytoplasm, N forms a nucleoprotein complex and the positive-strand RNA. In the endoplasmic reticulum-Golgi apparatus compartment (ERGIC), both complexes combine to achieve the virus replication process.⁴⁸ They are excreted via the vesicles and Golgi apparatus as mature viruses into the extracellular zone and liberated from cells to infect new ones.⁴⁹

Drug Repurposing Against SARS-CoV-2

On the other hand, drug repurposing^{26,28,50–56} is emerging as a good choice for COVID-19 treatment.^{57–65} Drug repurposing strategy can be utilized via the use of already-approved effective drugs that show a promising avenue for their reuse for other indications, such as combating COVID-19.^{22,66–75} Countries around the world are intensively trying to invent treatment or preventive measures against SARS-CoV-2.¹ To date, there is no existing evidence that suggests any specific, completely effective medication for the treatment of COVID-19 patients.^{19,76} More than 300 clinical research studies have already evaluated possible therapeutic strategies for COVID-19 prevention and/or treatment.³¹ The Centers for Disease Control and Prevention (CDC) and the World Health Organization (WHO) have proposed many guidelines for treatment including immediate intensive care, experimental antimicrobial agents, immune system boost, oxygen therapy, and others.²

Those facts motivated us to utilize the lessons learned during the coronavirus pandemic, review the latest developments, and forecast future research and technological development needs. So, many questions were discussed such as:

1. What are the mechanisms of the action and examples of antiviral materials found in technological and natural environments?
2. What are the farthest effective morphological and structural targets of SARS-CoV-2 that feasible antiviral agents' modes of action can be used for?
3. What are the potential determinations required to evaluate the capability of existing antivirals to affect SARS-CoV-2 specific targets?
4. What are the specific mechanisms and structural features that must be taken into consideration when developing new antiviral drugs in the future?³²

Despite this not being the first review article discussing the aforementioned issue,⁷⁷ in this article, we tried to be more professional in introducing facts, collecting nearly all the available data, and trying to be as up-to-date as possible. Therefore, we classified the FDA-approved repurposed drugs against SARS-CoV-2 into three main categories, antiviral drugs and non-antiviral drugs, besides the recently introduced convalescent plasma as well (Figure 2).

Antiviral Drugs for the Fight Against COVID-19 (Table 1)

Targeting RNA-Dependent RNA Polymerase (Reverse Transcriptase Inhibitors)

Remdesivir

Remdesivir is expanded to be used for Ebola treatment.⁷⁸ Ebola is a single-stranded RNA virus. Remdesivir appears as an adenosine analog that interferes with the viral RNA-dependent RNA-polymerase (RdRp)⁷⁹ and induces premature or delayed termination of the RNA chain.^{15,80,81} In vitro, its action is confirmed as an antiviral against respiratory viral pathogens including SARS-CoV-2. Similar protective effects are seen in vivo in SARS-CoV- and MERS-CoV-infected mice with low airway inflammation and improved lung function. Essentially, the effectiveness of post-exposure therapy depends on the time of drug administration.¹⁵

Furthermore, remdesivir's mechanism of action depends on the fact that nucleoside analogs have been licensed to treat DNA and RNA viruses. However, CoVs have been reported to be resistant to some nucleoside analog inhibitors.^{78,82} As a nucleoside analog, remdesivir acts as an RdRp inhibitor, targeting the viral genome responsible for the replication process. So, it inhibits the protein complex of CoVs in the RdRp process. After metabolizing remdesivir by the host to its active metabolite nortriptyline (NTP), this metabolite is conjugated to ATP, which incorporates it into the nascent RNA strand. This incorporation of the new strand results in RNA synthesis termination, halting the RNA strand growth after adding more nucleotides.

All CoVs have a proofread process capable of detecting and removing another nucleoside analog activity, thus preserving its antiviral activity. Unsurprisingly, Agostini et al noted that the mutant Murine hepatitis virus (MHV) was freed from proofread ability and was largely susceptible to remdesivir. It is also possible that mutations that improve the proofread or increase the accuracy of the base-pairing process may lead to remdesivir resistance. Indeed, Agostini et al

Figure 2 FDA-approved repurposed drugs against SARS-CoV-2.

also induced mutations in MHV (bypassing into remdesivir) that awarded sturdy resistance against the medication. It is unclear to what extent this experiment could represent a cause in which a resistance mutation would naturally develop. Furthermore, some evidence indicated that remdesivir might have another mechanism of action that might allow partial antiviral vitality to continue despite viral mutations.⁸²

Remdesivir was approved or authorized for emergency use by WHO. In November 2020, WHO updated a conditional recommendation against remdesivir in hospitalized patients. In this case, there is a conditional recommendation against the use of remdesivir.⁸³

Clinical Trials

To fight this outbreak, the phase III clinical studies on remdesivir, especially with its previous test findings and implementation, are of practical significance to obtain the more powerful antiviral drug for the potential tactical and political dominance of SARS-CoV-2.⁸¹

1. Clinical progress was documented in a series of 61 hospitalized patients receiving remdesivir off-license in 36 out of 53 patients with adequate data to examine. However, these results are difficult to understand without a placebo group. An initial randomized controlled study was inaccurate, preferring remdesivir, with a non-significant direction towards the decreased time to clinical changes. This study was inadequate; however, it revealed improved healing in patients treated with remdesivir (average recovery time of 11 days vs placebo of 15 days). Moreover, on day 14, there was progress for better survival. For those with high-flow oxygen, invasive ventilation, or non-invasive ventilation, the subgroup study showed a bit little advantage, indicating that antivirals such as remdesivir would have minimal effectiveness in late diseases where the phenotype is expected to be inflammatory. It should be noted that the analysis was published early and further follow-up research is required to yield entire results.¹⁵
2. Several clinical research types about the use of remdesivir for the prophylaxis from COVID-19 are pending. The National Institutes of Health (NIH) sponsored a clinical study in the USA and Korea. It is a double-blinded and

Table 1 Antiviral Drugs and Non-Antiviral Drugs That Could Be Repurposed Against COVID-19 Include Their Mode of Action, Original Use, and Chemical Structure

Drug	Classification	MOA	Original Use	Repurposing	Structure
Antiviral drugs for the fight against COVID-19					
Targeting RNA-dependent RNA polymerase (Reverse Transcription inhibitors)					
Remdesivir ⁷⁸	Antiviral agent	Targeting RNA-dependent RNA polymerase (Reverse transcription inhibitor)	Ebola's treatment	COVID-19's Treatment	
Favipiravir ⁹¹	Antiviral agent	Targeting RNA-dependent RNA polymerase (Reverse transcription inhibitor)	Influenza's treatment	COVID-19's Treatment	
Ribavirin ⁹⁰	Antiviral agent	Targeting RNA-dependent RNA polymerase (Reverse transcription inhibitor)	Treats viral infections (HCV, respiratory syncytial virus (RSV), and viral hemorrhagic fevers)	COVID-19's Treatment	
Tenofovir ¹⁰⁰	Antiviral agent	Targeting RNA-dependent RNA polymerase (Reverse transcription inhibitor)	Treatment of HIV or HBV chronic infection	COVID-19's Treatment	
Galidesivir ¹⁰⁰	Antiviral agent	Targeting RNA-dependent RNA polymerase (Reverse transcription inhibitor)	Ebola virus disease besides a lot of viruses' infections	COVID-19's Treatment	
Fusion inhibitors (Targeting Spike Protein)					
Umifenovir ⁹⁰	Antiviral agent	Fusion inhibitor	The prophylaxis and treatment of influenza A and B infections, HCV, HBV, and Ebola	COVID-19's Treatment	

(Continued)

Table I (Continued).

Drug	Classification	MOA	Original Use	Repurposing	Structure
Nafamostat mesylate ¹⁰⁷	Antiviral agent	Fusion inhibitor	Treats disseminated intravascular coagulation (DIC)	COVID-19's Treatment	
Camostat mesylate ¹⁰⁷	Antiviral agent	Fusion inhibitor	Treats DIC	COVID-19's Treatment	
Neuraminidase inhibitors					
Oseltamivir ¹¹⁵	Antiviral agent	Neuraminidase inhibitor	Treatment of influenza	COVID-19's Treatment	
Zanamivir ^{113,114}	Antiviral agent	Neuraminidase inhibitor	Treatment of influenza	COVID-19's Treatment	
Peramivir ^{113,114}	Antiviral agent	Neuraminidase inhibitor	Treatment of influenza	COVID-19's Treatment	
Protease inhibitors					
Lopinavir ¹¹⁸	Antiviral agent	Protease inhibitor	Treatment of HIV infection	COVID-19's Treatment	

Danoprevir ¹²⁴	Antiviral agent	NS3/4A protease inhibitor	Treatment of HCV infection	COVID-19's Treatment	
Darunavir ¹²⁶	Antiviral agent	Protease inhibitor	Treatment of HIV infection	COVID-19's Treatment	
Atazanavir ¹²⁸	Antiviral agent	Protease inhibitor	Treatment of HIV infection	COVID-19's Treatment	
Saquinavir ¹³¹	Antiviral agent	Protease inhibitor	Treatment of HIV infection	COVID-19's Treatment	
Indinavir ¹³¹	Antiviral agent	Protease inhibitor	Treatment of HIV infection	COVID-19's Treatment	
Amprenavir ¹³¹	Antiviral agent	Protease inhibitor	Treatment of HIV infection	COVID-19's Treatment	

(Continued)

Table I (Continued).

Drug	Classification	MOA	Original Use	Repurposing	Structure
Raltegravir ¹³¹	Antiviral agent	Protease inhibitor	Treatment of HIV infection	COVID-19's Treatment	
Paritaprevir ¹³¹	Antiviral agent	Protease inhibitor	Treatment of HIV infection	COVID-19's Treatment	
Niclosamide ⁵⁸	Antiviral agent	Protease inhibitor	Treatment of worm infections. Also, SARS-CoV, MERS-CoV, ZIKV, JEV, HCV, EBOV, HRVs, CHIKV, HAAdV, and EBV.	COVID-19's Treatment	
Nelfinavir ¹⁴¹	Antiviral agent	Protease inhibitor	Treatment of HIV infection	COVID-19's Treatment	
Ebselen ¹⁰⁰	Antiviral agent	Protease inhibitor	Treatment of neurodegenerative diseases	COVID-19's Treatment	
M2 ion-channel protein blockers					
Amantadine ^{151,152}	Antiviral agent	M2 ion-channel protein blocker	Treatment of influenza viruses	COVID-19's treatment	

Adamantane ^{151,152}	Antiviral agent	M2 ion-channel protein blocker	Treatment of influenza viruses	COVID-19's treatment	
Rimantadine ^{151,152}	Antiviral agent	M2 ion-channel protein blocker	Treatment of influenza viruses	COVID-19's treatment	
Non-Antiviral drugs that have antiviral activity against SARS-CoV-2 infection					
Ivermectin ¹⁰⁰	Antiparasitic agent	Protease inhibitor	Treatment of HIV and Dengue virus infections	COVID-19's treatment	
Interferon-Alpha/Beta ^{153,162}	Immune stimulating agent	Initiation of JAK-STAT signaling cascades	Treatment of HBV, HCV, autoimmune disorders, and malignant tumor	COVID-19's treatment	
Chlorpromazine ¹⁰⁰	Antipsychotic, Anxiolytic, Antiemetic, antiviral, and antifungal agents	Inhibits the assembly of Clathrin lattices and prevents the entry of the virus into host cells.	Treatment of manic-depression or schizophrenia, vomiting, nausea, anxiety, acute intermittent porphyria, and chronic hiccups	COVID-19's treatment	
Emetine ¹⁶⁶	Anti-protozoan agent	Inhibits the low-micromolar spectrum and replication of coronaviruses	Treatment of Ebola virus, Zika virus, HIV, Cytomegalovirus, Newcastle virus, fever virus of the Rift River, and influenza viruses, etc.	COVID-19's treatment	

(Continued)

Table I (Continued).

Drug	Classification	MOA	Original Use	Repurposing	Structure
Aplidine ¹⁶⁷	Antiviral agent	Inhibits the spread and multiplication of the virus	Treatment of multiple myeloma	COVID-19's treatment	
Teicoplanin ¹⁶⁹	Antibiotic agent	Prevents the release of the viral genome RNE and the viral replication cycle	Treatment of streptococcal, staphylococcal infections, HIV, influenza virus, hepatitis C, flavivirus, Ebola, SARS -CoV, and MERS -CoV.	COVID-19's treatment	
Baricitinib ¹⁷²	Anti-inflammatory and Immunosuppressive agent	A Janus kinase (JAK) inhibitor (Fusion inhibitor)	Treatment of cancer and inflammatory diseases such as rheumatoid arthritis (RA)	COVID-19's treatment	
Ruxolitinib ⁴⁹	Anti-inflammatory and Immunosuppressive agent	A Janus kinase (JAK) inhibitor (Fusion inhibitor)	Treatment of cancer and inflammatory diseases such as rheumatoid arthritis (RA)	COVID-19's treatment	
Fedratinib ⁴⁹	Anti-inflammatory and Immunosuppressive agent	A Janus kinase (JAK) inhibitor (Fusion inhibitor)	Treatment of cancer and inflammatory diseases such as rheumatoid arthritis (RA)	COVID-19's treatment	
Rapamycin ¹⁷⁵	Antifungal and immunosuppressive agent	Immunosuppressant; PI3K/mTOR inhibitor that inhibits the viral replication	Andes virus, HCV, Middle-East respiratory syndrome coronavirus (MERS-CoV), and H1N1 pneumonia	COVID-19's treatment	

placebo-controlled experiment under which participants are randomized to administer either a placebo or a preliminary dose of 200 mg of intravenous remdesivir on the first day, preceded by a controlled dose of 100 mg a day, up to a limit of 10 cumulative days of care by discharge. As described in the United States National Library of Medicine clinical trials registry, the primary trial outcome is expressed as the proportion of patients in each category (seven-category clinical severity scale is used) till the fifteenth-day post-treatment initiation. Also, Gilead Sciences funds a remdesivir analysis with a combined primary outcome test of fever and oxygen normalization in patients with extreme COVID-19.⁸⁰

3. Two double-blinded placebo-controlled trials are also recruiting in Hubei Province, China: One study was for mild-to-moderate COVID-19 admitted patients, while the other was based on serious cases.⁸⁰ The primary success indicator for the mild-to-moderate research study is timely clinical rehabilitation, as described by the normalization of the body temperature, breathing rate, oxygen consumption, and coughing recovery for at least 72 hours. In the extreme case study, the primary result is time for health progress and is described using a six-category ratio scale from discharge to mortality.⁸⁰
1. Previous research has also revealed that remdesivir was effective against MERS-CoV, decreasing the viral loads in the infected portion of mice, and helping in normal lung-based function restoration.⁸⁴ Also, It is considered to be a treatment-assisted agent versus SARS-CoV-2.⁷⁸ Preliminary research showed that remdesivir administration for about 12 days could decrease the viral load in oropharyngeal and nasopharyngeal swabs.⁸⁵
2. In an in vitro analysis, chloroquine – an anti-malarial drug – and remdesivir combination can effectively block the development of SARS-CoV-2 in cells of Vero E6.⁸⁶ Clinical studies in Norway, France, and the USA are underway to determine the potency of remdesivir in COVID-19. COVID-19 Cases in Singapore and the USA were treated with remdesivir, and the first patient got recovered in the USA by administering it intravenously.⁸⁵
3. Another study among 596 patients, 584 received remdesivir or continued standard care, and 533 (91%) completed the trial. The average length of treatment was 5 days for patients in the 5-day remdesivir group and 6 days for patients in the 10-day remdesivir group. On day 11, patients in the 5-day remdesivir group had statistically significantly higher odds of a better clinical status distribution than those receiving standard care.⁸⁷
4. However, a trial outcome concerning safety, viral load, and secondary outcomes. Twenty-two (14%) of 158 patients on remdesivir died versus ten (13%) of 78 on placebo, and there was no signal that viral load decreased differentially over time between remdesivir and placebo groups.⁸⁸

However, the prophylactic use of remdesivir is generally restricted by its poor oral bioavailability. Further pharmacological efforts are needed to make the drug accessible to the outpatient population. Recently, the manufacturer announced in an open letter that a Phase 1 trial with remdesivir inhalation is being planned and already accepted by the FDA.⁸⁹

The dosage type of remdesivir used during clinical studies is a freeze-dried powder injection. Thus, the dosage system used is: on the first day, 200 mg as an initial dose of remdesivir is administered by intravenous dripping. Then, 100 mg as a maintenance dose is administered by intravenous dripping per day for 9 days.⁹⁰

Favipiravir

Favipiravir is a purine analog. It was approved in Japan to treat influenza. Also, it is selective against some RNA viruses in vitro, including SARS-CoV-2. In mice, favipiravir increased the survival of the influenza A virus.¹⁵ It is known to be active in vitro against oseltamivir-resistant A, B, and C viruses. After its transformation to the active phosphoribosylated form, favipiravir is considered as a substrate of viral RNA polymerase in many RNA viruses.⁹¹

In the tissue, the enzyme phosphoribosylated it to its active form favipiravir-RTP. The following different pathways explain the favipiravir mechanism of action:

- (a) It is mistaken as a purine nucleotide by the RNA-dependent RNA-polymerase (RdRp) enzyme, which acts as a substrate molecule, thus its action is stopped putting an end to viral protein replication.⁹²

- (b) This mode of action along with maintaining the RdRp enzyme by the catalytic domain illustrates the wide variety of activities this compound can do by preventing further extension and integrating into the RNA viral chain.⁹³
- (c) Favipiravir is a virucidal drug. It is committed to causing *in vitro* fatal mutagenesis during influenza infection. However, it is not known whether Favipiravir has a similar activity against SARS-CoV-2 or not yet.⁹⁴

Favipiravir is a drug given orally and has a similar mechanism of action to remdesivir. Favipiravir has less supporting evidence to justify its application. However, it is still emerging as an agent that is worth trying out for mild-to-moderate situations.⁹⁴ Favipiravir's main advantage is primarily oral administration. So, it can be given as a part of the hospital treatment for cases having symptoms but are not extremely ill. Given that so many COVID-19 cases have mild to moderate accompanying diseases and care should be received at home, hence this medication may likely be used in multiple cases. Viremia reduction is observed when favipiravir is early administered after COVID-19 symptoms appear. In an ongoing experiment, the action of favipiravir on prophylaxis is also investigated.⁹⁴ On the other hand, its main disadvantage is heavy pill pressure, which results in 18 tablets filled on the first day and 8 tablets per day for the remainder of the treatment course. These worries about the heavy pill pressure are being partly alleviated with the recent introduction of a 400 mg dose. A disadvantage can also be a prescribed medication period of up to 2 weeks. Favipiravir's teratogenicity is the most important adverse effect.

Besides, other adverse effects like increased uric acid, neutropenia, diarrhea, and elevated ALT and AST during phase III clinical study in the global multi-center patients in Japan. In a randomized controlled trial of favipiravir in cases with COVID-19, psychiatric, hepatic enzyme disorders, serum elevation of uric acid, and gastrointestinal symptoms were the most common adverse effects. The overall favipiravir side effects were moderate even though it should not be taken by pregnant women.^{90,94}

Clinical Trials and Combination Therapy

Favipiravir is approved for the care of novel or persistent influenza in Japan. Besides, it was one of the first approved drugs for controlling COVID-19.^{10,90,94} In China, the prescribed dosage of favipiravir in influenza is 1600 mg delivered orally every 12 h on the 1st day, followed by 600 mg orally every 12 h, and 600 mg every 24 h on the 6th day.⁹⁰

Moreover, randomized trials containing (interferon- α and favipiravir) or (baloxavir, marboxil, and favipiravir) were recruited for patients with COVID-19 infections.⁹¹ The combination with other antivirals like umifenovir is often tested to assess whether the treatments are synergistic or complementary.⁹²

In an open-label non-randomized study in China, SARS-CoV-2 patients who were treated with a double combination interferon- α /favipiravir in contrast to triple combination interferon- α /ritonavir/lopinavir showed a shorter time for viral clearance (four days vs eleven days, respectively) and a much better improvement of the chest X-ray.¹⁵

Ribavirin

Ribavirin is an analog of guanosine^{90,91} with a wide range of RNA antiviral activity. It is used in the treatment of many viral diseases, including respiratory syncytial virus (RSV), hepatitis C virus (HCV), and some hemorrhagic viruses. It was determined to have 50 mg/mL of *in vitro* antiviral activity with SARS-CoV. However, lowering hemoglobin, which is harmful to people suffering from respiratory failure, is an undesirable side effect.⁹¹ The most extreme adverse effects of ribavirin are hemolytic anemia and reproductive toxicity.⁹⁵ Lethal mutagenesis, non-specific or specific chain end-up and nucleotide biosynthesis inhibition are involved in the antiviral processes of ribavirin.⁹⁶

Ribavirin is used in China for COVID-19 cases listed in the Chinese government. The dose for adults is 500 mg, from 2 to 3 times daily by intravenous infusion, and for a duration not exceeding 10 days. It is advised to use ribavirin in combination with ritonavir/lopinavir or interferon.⁹⁰

Clinical Trials and Combination Therapy

In another retrospective review of 126 patients undergoing therapy with ribavirin (the dose is 2000 mg), the side effects of the drug were tracked. Some patients showed elevated transaminase (40%), hemolytic bleeding, and bradyarrhythmia (14%).⁹⁷ Therefore, the dose of ribavirin must be monitored cautiously to treat COVID-19 patients.⁸⁰ Ribavirin was also

tested with contradictory findings in the past outbreaks of MERS-CoV and SARS-CoV. Concerning SARS-CoV-2, a randomized Phase II clinical trial of a total of 127 patients recruited with mild/moderate COVID-19 was performed to suppress virus replication in the micromolar stages.⁹⁸

Applying ribavirin/interferon-beta to ritonavir/lopinavir is more recommended than ritonavir/lopinavir alone.⁹⁹

Furthermore, Ivermectin and nitazoxanide, anti-parasitic drugs, are shown to potentiate interferon-alpha and beta effects and subsequently the immune responses. They were studied with ribavirin for COVID-19 cases without comorbidities. However, the clinical trials described above are not adequate to explain the successful ribavirin contribution to the progression of the disease. In the case of hospitalizing adult cases with COVID-19, a Phase I review, on the other hand, assessed inhaled ribavirin preparation as a sole agent.¹⁰⁰

Tenofovir

It is a nuclear adenosine analog prescribed for the treatment of chronic HBV or HIV infections. Tenofovir can efficiently integrate into RNA-dependent RNA polymerase terminating the polymerase reaction. In combination with emtricitabine, tenofovir is considered a highly effective portion of HIV-contaminated antiretroviral treatment and a first-line alternative to HIV prophylaxis before and after exposure.¹⁰⁰

Clinical Trials

Inconsistent with the above therapeutic method, two randomized phase III clinical studies using emtricitabine/tenofovir were carried out for prophylaxis purposes before the exposure to COVID-19 in health care staff.¹⁰⁰

Galidesivir

Galidesivir is an analog of adenosine^{90,91} that replaces carbon with nitrogen on a base at position 7 and replaces nitrogen with oxygen on a ribose ring at position 1.⁹² The structural alteration changes the electrostatic interaction with the viral RNA polymerase, leading to the untimely end-station of the extended RNA strand.¹⁰¹ Galidesivir has shown a broad spectrum of antiviral activities,^{100–102} including Togavirus, Filovirus, Arenavirus, Bunyavirus, Paramyxovirus, Coronavirus, Flavivirus, one Picornavirus, and one Orthomyxovirus, and it is currently ongoing as an antiviral treatment for Ebola.^{101,103} This drug prevents SARS-CoV, SARS-CoV-2, and MERS-CoV infection in primary human cell cultures, thereby improving pulmonary function and decreasing the viral load. The antiviral results showed its ability to incorporate several lethal mutations through viral RNA, however being not through host RNA, hence that would cause a high barrier to drug resistance development.¹⁰⁰

Clinical Trials

In a pilot sample, galidesivir was also demonstrated to provide partial protection for Rift Valley Fever Virus (RVFV) infection in the mouse model.¹⁰² Effectiveness has been documented more recently in models for tick-borne Flavivirus and Zika infection. Besides, phase I human research on galidesivir administered intramuscularly against placebo in healthy people concluded strong tolerability and promising pharmacokinetics characteristics.^{101,103}

Other Nucleoside/Nucleotide Analogs (Other Transcription Inhibitors)

Other nucleoside and nucleotide analog drugs can be considered. They are either dedicated to various viral infections (eg telbivudine, sofosbuvir, tenofovir, and ribavirin) or scientifically investigated (eg EIDD-2801, and galidesivir).¹⁰⁰ Due to their related structural properties with either ribavirin or remdesivir, they are likely to have antiviral action against SARS-CoV-2. Some have been approved by FDA as Nucleoside Analog Reverse Transcriptase Inhibitors (NtRTIs), such as tenofovir, alafenamide, adefovir, tenofovir, disoproxil, didanosine, ganciclovir, and abacavir. Furthermore, the antiviral activity against SARS-CoV-2 can also be revealed with other inhibitors including Non-Nucleoside Reverse Transcriptase Inhibitors (NNRTIs) such as nevirapine, efavirenz, rilpivirine, and delavirdine, and Nucleoside Reverse Transcriptase Inhibitors (NRTIs), such as stavudine, lamivudine, emtricitabine, azvudine, and zalcitabine. In addition, although some *in silico* trials have already been assessed by molecular docking, further preclinical and clinical trials should be carried out to assess their clinical effectiveness.⁴⁹

In conclusion, ribavirin and sofosbuvir can be closely bound to the newly developed RdRp coronavirus and hence interfere with the protein function resulting in viral eradication. It is worth mentioning that Sofosbuvir acts as a potent inhibitor of the recently emerging COVID-19 type of HCoV.¹⁰

Targeting Spike Protein (Fusion Inhibitors)

Umifenovir

Umifenovir is a short indole derivative that provides a range of action against RNA and DNA viruses. These viruses are host targeting and directing, thus preventing the viral entry via host cell (internalization/attachment).⁹⁰

It is approved (only in China and Russia) for the prophylaxis and treatment of influenza A and B infections.¹⁰⁴ However, it has demonstrated an *in vitro* efficacy against infections caused by Hepatitis B and C viruses (HBV and HCV), Ebola, and other viruses.

Clinical Trials

In Russia, Umifenovir was initially approved to treat influenza in 1993. The medication is now sold in Russia and China to treat upper respiratory influenza A and B infections.⁹⁴ In the “Treatment Scheme and New Coronavirus Pneumonia Diagnosis”, umifenovir is recommended for patients with COVID-19. It is administered for adults as 0.2 g, 3 times daily, for 10 days.⁹⁰

In the clinical studies, oral therapy with umifenovir was shown to suppress mortality and viral load in comparison to other unspecified antiviral drugs or the control group obtaining interferon.¹⁰⁵ It has moderate overall side effects, such as abdominal discomfort, nausea, headache, leukopenia, elevated bilirubin, and elevated alkaline phosphatase (AKP). Retrospective trials to determine the safety and efficacy of umifenovir therapy in patients with COVID-19 showed no significant adverse effects in the course of treatment.⁹⁰

Camostat Mesylate

Camostat mesylate is an inhibitor of serine protease¹⁰⁶ and is another medication that targets the fusion of viruses. Inside the targeted host cells, SARS-CoV-2 gains access to TMPRSS2 and/or ACE-2 receptors.⁹⁶ Camostat mesylate works as a TMPRSS2 inhibitor.¹⁰⁷ The SARS-CoV-2 spike (S) protein is downregulated to inhibit the virus from entering the cell and thus inhibit surface fusion.¹⁰⁸

Clinical Trials

One previous research showed that camostat mesylate blocked the entry of SARS-CoV into human epithelial bronchial cells.¹⁰⁹ In a further *in vitro* analysis, camostat mesylate and E-64d (a cysteine protease inhibitor) have shown effective SARS-CoV-2 TMPRSS2 inhibition.³³

The efficacy of hydroxychloroquine and camostat mesylate combination therapy in Denmark and Germany has been tested.⁴⁹ A 15-fold greater efficiency for SARS-CoV-2 virus entry into the host cells was observed in another serine protease inhibitor, nafamostat mesylate. Nafamostat mesylate can be considered as a safer alternative to camostat mesylate because nafamostat has more efficient antiviral activity and a favorable safety profile.¹¹⁰ Besides, disseminated intravascular coagulation (DIC) with increased fibrinolysis shown in COVID-19 patients is also treated with nafamostat mesylate.⁴⁹

Neuraminidase Inhibitors

Oseltamivir

Oseltamivir is a neuraminidase inhibitor.¹¹¹ It is successful in avoiding influenza and is effective in the treatment of influenza in children.¹¹² Neuraminidase inhibitor medicines like zanamivir, peramivir, and oseltamivir are not anticipated to be effective for SARS-CoV-2 and are not recommended for COVID-19 patients treatment^{113,114} because SARS-CoV-2 neuraminidase has not been found yet.¹¹⁵

Clinical Trials and Combination Therapy

Studies showed that ganciclovir with oseltamivir or ritonavir/lopinavir with oseltamivir is used for the treatment of

COVID-19 in Wuhan patients.¹¹⁵ The synergistic effects of ritonavir/lopinavir combination with oseltamivir in SARS-CoV-2 were also confirmed by computational studies.¹¹⁶ In Afghanistan, oseltamivir was used for treating COVID-19 cases with terbutaline and ceftriaxone. Moreover, a case study also showed that the CT scan of the patients' lungs was greatly improved after three days of oseltamivir administration. Oseltamivir is used in Singapore and Indonesia as the recommended alternative to treat COVID-19.⁴⁹

Oseltamivir is used by the oral route of administration for the treatment of COVID-19 and suspected patients in Chinese hospitals, but until now, there is no conclusive evidence that it has a true effect on COVID-19 patients' recovery.¹¹⁴

Zanamivir and Peramivir

Zanamivir solution is also one of the neuraminidase inhibitors that can be applied for ventilated COVID-19 patients resistant to oseltamivir treatment. Also, Peramivir is used by intravenous route of administration as an antiviral drug. It has some benefits for patients who give no response to zanamivir or oseltamivir.^{113,114}

Oseltamivir was orally used in Chinese hospitals to treat 2019-nCoV confirmed cases. However, there is no definitive proof that oseltamivir may be useful for COVID-19 patients' treatment. In addition, neuraminidase inhibitors including zanamivir, peramivir, and oseltamivir have recently been proposed to be ineffective against nCoV-2019 and hence are not recommended to be used for treatment protocols.¹¹³

Protease Inhibitors

Lopinavir

Lopinavir is used with ritonavir to treat and prevent HIV infection. Furthermore, Lopinavir is reported to inhibit SARS-CoV-2 at a half-maximal efficient concentration (EC_{50}) of 2.660/1.671.¹⁰⁰ Its administration as an emergency drug in China elevated the eosinophil count among COVID-19 cases.¹¹⁷ An *in silico* study showed promising effects of ritonavir and lopinavir combination (both are HIV protease inhibitors) as SARS-CoV-2 main protease (Mpro) inhibitors.⁹ An earlier study showed that a specific combination of lopinavir/ritonavir, known as Kaletra[®] showed antiviral effects against SARS-CoV in both *in vitro* and clinical trials.¹¹⁸ Therefore, this combination is also being used as a contingency treatment for COVID-19 patients in several countries.¹¹⁹

Clinical Trials and Combination Therapy

A previous study showed that treatment with lopinavir/ritonavir was correlated with better results but did not enhance the clinical recovery of the seriously infected COVID-19 patients.¹¹⁹ Although the effectiveness of lopinavir for COVID-19 treatment has not been tested yet, the combination of ritonavir/lopinavir is used for treating COVID-19 patients in some countries like Japan, Singapore, and the USA. Clinical studies are underway to determine the effectiveness of lopinavir/ritonavir for COVID-19 in Thailand, Spain, Canada, China, Hong Kong, France, and the United States.⁴⁹

In addition, interferon (INF)- β (an inflammation-regulating molecule) alone or in combination with lopinavir/ritonavir was a "solidarity" clinical trial for coronavirus that has been listed by the WHO.¹⁰⁰ Besides, the lopinavir/ritonavir combination can improve the clinical symptoms and reduce the viral load of COVID-19 patients.¹⁰⁵

Lopinavir/Ritonavir + Ribavirin

The protease inhibitors recommended in a combination form (Kaletra[®]) are ritonavir (RTV) and lopinavir (LPV).⁹⁰ Kaletra[®] is a specific preparation to treat HIV.¹⁵

Lopinavir is an inhibitor of the HIV protease,¹¹¹ which may weaken the virus infection rate and affect the formation of mature virus particles. Short half-life and low bioavailability are characteristic of lopinavir.⁹⁰ Lopinavir is an HIV protease inhibitor, which can influence the formation of mature virus particles and weaken the infectivity of the virus.

On the other hand, Ritonavir is an inhibitor of the cytochrome CYP3A4 enzyme, which decreases the metabolism of lopinavir by suppressing the cytochrome P450. The combined treatment of ritonavir and lopinavir can increase the bioavailability of lopinavir *in vivo*.^{14,90} Ribavirin is an analog of guanosine that can stop RdRp-mediated RNA viral chain elongation.¹⁵

Clinical Trials

Ritonavir and lopinavir treatment combination dramatically increase lopinavir's bioavailability and increase the antiviral activity in vivo.⁹⁰

Prophylactic ritonavir/lopinavir-Interferon- β was moderate in viral load decrease for Murine's infection of MERS-CoV relative to remdesivir. However, no major post-infection effects on viral load, acute lung damage, or lung bleeding were observed.^{15,120}

Ritonavir and lopinavir tablets can be taken every 12 hours for not less than 10 days and a total of 14 days (400 mg/100 mg of lopinavir/ritonavir). Children's doses are regulated based on body weight: 10 mg/kg for 15–40 kg and 12 mg/kg for 7–15 kg at the full dose of 400/100 mg a time. If the history of symptoms is <7 days, interferon- β 1a is given in combination with ritonavir/lopinavir on a 44 μ g dosage for 3 doses every six days.¹²¹

Lopinavir/Ritonavir + Umifenovir

Patients who received the triple combination treatment of lopinavir/ritonavir plus umifenovir showed an advantage to curb disease development compared to lopinavir/ritonavir alone. Also, the combination of ritonavir/lopinavir and umifenovir significantly stopped the advancement of lung damage.⁴⁹

Danoprevir

Danoprevir is a potent inhibitor of hepatitis C proteases.^{122,123} It has been approved as an oral antiviral medication in China by 2018 for the treatment of hepatitis C. Hence, it was repurposed as a drug for the treatment of COVID-19.¹²⁴

Clinical Trials

Phase III clinical studies on 140 cases showed that a triple combination of pegylated-interferon α -2a, ritonavir-boosted danoprevir, plus ribavirin achieved a sustained virologic response within 12-week (SVR12) after treatment in Chinese infected cases with non-cirrhotic hepatitis C virus.¹²⁴ In the other two clinical trials, phase II and Phase III, the rate of SVR12 in infected cases was about 99% in the complete oral treatment of non-cirrhotic HCV using the triple combination of ribavirin with ritonavir-boosted danoprevir and ravidasvir (an inhibitor of HCV NS5A).¹²⁵

Darunavir

Darunavir, an anti-HIV drug, has been recommended for the treatment of COVID-19 in Italy.¹²⁶ It can be used in a concerted regimen with cytochrome P-450 inhibitors such as cobicistat or ritonavir. Moreover, in vitro studies have shown its promising anti-proliferative effect against SARS-CoVs.¹²⁶

Clinical Trials

In Thailand, a clinical trial is underway to evaluate the efficacy of darunavir's combination with other drugs, such as hydroxychloroquine and antivirals for coronavirus patients. Besides, the combination of cobicistat and darunavir was examined in an outstanding clinical trial in China. Thus, a fixed-dose integration of cobicistat and darunavir, known as prezcobix[®], may also be used for COVID-19 treatment.⁴⁹

Newly, HIV-positive patients who were already undergoing treatment with darunavir were subjected to COVID-19 infection, raising the interest in the effectiveness of this HIV protease inhibitor.¹²⁷ This indicates that darunavir may not be effective for SARS-CoV-2 infection prevention at the present approved dose of 800 mg.⁴⁹

Atazanavir

An in-silico study reported that atazanavir is stronger than lopinavir at the binding site in SARS-CoV-2 M^{Pro}. Besides, an in-vitro study revealed that SRS-CoV-2 replication was inhibited using atazanavir.¹²⁸

Clinical Trials

Research on HIV-infected people revealed that increased lipid parameters and glucose absorption are associated with ritonavir/atazanavir use compared to lopinavir/ritonavir.¹²⁹ Also, it is found that if atazanavir is paired with ritonavir it will give the same action in the combination of lopinavir/ritonavir, hence atazanavir could be an alternative to lopinavir.

However, further research trials should be carried out. This antiviral medicine is currently an alternative for the treatment of COVID-19.¹³⁰

Saquinavir and Other Protease Inhibitors

Due to the high degree of similarity between their chemical structures, saquinavir and other protease inhibitors, such as indinavir, amprenavir, and nelfinavir, can also exhibit similar effects against COVID-19 as protease inhibitors as described earlier.¹³¹

Clinical Trials

An in-silico study showed that 3CL^{Pro} activity in SARS-CoV-2 could be inhibited by saquinavir and indinavir.⁵⁹ Another research study found that SARS-CoV-2 was inhibited in-vitro by saquinavir, indinavir, amprenavir, and nelfinavir.¹³² However, saquinavir provides the strongest inhibition compared to others. Saquinavir has been used in the treatment of Singapore's COVID-19 patients. In addition, two more candidates, raltegravir and paritaprevir, were studied in another in silico study and demonstrated inhibitory effects on 3CL^{Pro} of SARS-CoV-2.¹³³

Potent anti-viral phytochemicals that may have inhibitory action against SARS-CoV-2 3CL^{Pro}¹³⁴ have recently been detected through medicinal plant library screening. Hence, the top reported antiviral candidates could be further tested by performing in-vitro studies.^{49,133}

Niclosamide

Niclosamide is an FDA approved anthelmintic drug used for the treatment of different nanomolar to micromolar viral infections including Middle East respiratory syndrome coronavirus (MERS-CoV), severe acute respiratory syndrome coronavirus (SARS-CoV), Japanese encephalitis virus (JEV), Zika virus (ZIKV), Ebola virus (EBOV), hepatitis C virus (HCV), Chikungunya virus (CHIKV), human rhinoviruses (HRVs), Epstein-Barr virus (EBV), and human adenovirus (HAdV). Because of its low cost and low in vivo toxicity profiles as clinically recognized FDA products, niclosamide's wide spectrum antiviral action can give it the therapeutic potential for the battle of rapidly propagating COVID-19.⁵⁸

Clinical Trials

Wu et al observed that, after the screening of a limited commercialized drug library, niclosamide could prevent SARS-CoV replication and eliminate the viral antigen replication.¹³⁵

The cytopathic effect (CPE) of SARS-CoV was blocked by niclosamide, and the virus replication was inhibited in Vero E6 cells. The SARS-CoV 3CL^{pro} has an important role in the production of polyproteins and serves as a central tool for the detection of anti-SARS medications.¹³⁶⁻¹³⁸

A series of 2-chloro-4-nitroaniline derivatives were revealed as potent inhibitors against SARS-CoV 3CL^{pro}. Interestingly, niclosamide showed no obvious inhibitory activity against SARS-CoV 3CL^{pro} up to 50 μ M, and it may exert its anti-SARS activity mechanistically via other modes of action. Furthermore, it has been documented that niclosamide inhibits MERS-CoV replication by a factor of up to 1000 at 48 h.p.i.⁵⁸

Nelfinavir

Nelfinavir is an inhibitor of HIV-1 protease intended for use as an antiviral that attacks HIV through alternative pathways. It has gone out of favor with the advent of novel hybrid antivirals for HIV.¹³⁹

Nelfinavir's mechanism of action includes that it prevents the processing of working proteins essential for HIV and binds to the HIV-1 protease active site. So, what is left are unsustainable, non-infectious HIV spores.¹³⁹ It was revealed as a possible agent with SARS-CoV inhibitory activities based on in-vitro experiments during the SARS epidemic.¹⁴⁰ It was reported to prevent the replication of SARS CoV.¹⁴¹

Nelfinavir has the most positive effect against SARS-CoV-2 out of the 30 pharmaceuticals evaluated. Its effectiveness against SARS-CoV or SARS-CoV-2 in individuals has not been tested yet. It is advised to use 750 mg per mouth 3 times daily or 1250 mg per mouth twice daily for the treatment of HIV. Its effective dose for the treatment of COVID-19 is unknown.¹⁴² Pharmacokinetics can be variable in nelfinavir patients with chronic hepatic disease.^{143,144} It has common

side effects like gastrointestinal intolerance, especially flatulence, diarrhea, and nausea. There may also be a non-specific rash.¹⁴²

Ebselen

Ebselen is a compound of organoselenium that decreases peroxyxynitrite and hydroperoxides and acts as a peroxiredoxin mimetic enzyme and glutathione peroxidase.¹⁴⁵ Some protein thiols interact with ebselen through a selenosulfide link, resulting in pleiotropic, anti-inflammatory, and antibacterial actions besides its main activity as an antiviral drug. A possible drug target is the Mpro of SARS-CoV-2, and ebselen was described as a promising inhibitor of Mpro by a panel of over 10,000 substances.¹⁰⁰

Ebselen's function is recognizing the cysteine proteases in viruses and other micro-organism infections. Besides, it affects the inflammation of the lung. Also, ebselen can act as an effective lead compound to suppress Mpro in SARS-CoV-2, and its inhibitory action was reported in vivo in adherent cells. Regardless of this action, modulation of cytokines and inflammatory oxidants are important pathogenetic goals, which are credited in COVID-19 to make potential benefits.¹⁰⁰

Clinical Trials

Early research of comprehensive ebselen reported various biological pathway targets, such as enzymes associated with inflammatory reactions, were identified for different clinical conditions.^{146–148} Tolerability and safety are strong, and no scientific trials have demonstrated any side effects.¹⁴⁹ It is discarded and metabolized as glucuronidated and methylated conjugates without selenium in its portion.^{100,150}

Ebselen also has an anti-inflammatory function in vivo, leading to its possible involvement in host reactions to viral infections.⁹⁰ It also blocks the development of oxidized compounds in brain tissue from HIV encephalitis and macaques with Simian immune deficiency virus encephalitis.⁹⁶ It is proposed that the therapeutic ability of ebselen could be used to block the symptoms of neurological HIV-1 infection in the brain.⁹⁰

M2 Ion-Channel Protein Blockers

Adamantane, Amantadine, and Rimantadine

The M2 channel protein on the viral sheath is essential for maintaining the pH across the viral sheath. It is critical for cell entrance and movement through the trans-Golgi membrane of steward cells pending viral maturation. Ion channel protein M2 is one of the targets for fighting influenza viruses.¹⁵¹

Clinical Trials

An early study showed that amantadine can block the p7 protein of HCV that is important for making ion channels in host cell membranes. A report in 1973 claimed that amantadine has a strong in vitro effect against coronavirus.¹⁵¹ Moreover, a recent report showed that amantadine can block protein-membrane channel activity for SARS-CoVs.¹⁵² Despite mounting evidence indicating that amantadine has an antiviral efficacy suitable for treating COVID-19,¹⁵³ other studies are pledged to evaluate its effectiveness.⁴⁹

Non-Antiviral Drugs That Have Antiviral Activity Against SARS-CoV-2 Infection

Importin α/β -Mediated Nuclear Import Inhibitors (Ivermectin)

Ivermectin is an FDA-approved anti-parasitic drug. It has also been shown to be a successful anti-viral for humans (HIV) as well as the Dengue virus.^{100,154} Thus, a single dose of the medication has lowered viral RNA about 5000 times.¹⁵⁵ Besides, it can isolate the pre-formed importin α/β heterodimer that transmits the viral protein charge nuclearly.⁴⁹ Since the suppression of nuclear transportation of viral protein is crucial to the host antiviral activity, so ivermectin is considered a therapeutic potential inhibitor to RNA viruses targeting the nuclear transport mechanism.^{155,156}

Clinical Trials and Combination Therapy

Recently, an *in vivo* study demonstrated the activity of ivermectin to minimize the viral RNA to 5000 times after 48 h of SARS-CoV-2 infection.¹⁰⁰ Another trial to show ivermectin's effectiveness in treating COVID-19 includes research to determine the optimal dosage using the proven safety profile for anti-parasitic treatment.^{44,157} However, further assessment is required for its effectiveness in the battle against COVID-19.

Ivermectin also showed a wide-spectrum antiviral activity. It inhibits the replication of the yellow fever virus directly by inhibiting the activity of NS3 helicase.¹⁵⁸ It also prevents the replication of HIV-1 and dengue viruses¹⁵⁴ by preventing importin $\alpha/\beta 1$, which promotes the movement of proteins between the nucleus and cytoplasm, essential for the replication of these viruses.^{45,158}

In a recent case-controlled retrospective study, it was proposed that the length of the hospital stays and the risk of mortality decreased by ivermectin treatment at a dose of 150 mcg/Kg. Further, randomized controlled clinical trials are needed in patients infected with SARS-CoV-2 before confirming the effectiveness of ivermectin.⁴⁹

Combination therapy of hydroxychloroquine and ivermectin was suggested for the treatment or prophylaxis of COVID-19. This combination may have a synergistic impact due to its dual action on both viral replication and viral assembly.¹⁵⁹ Although the pharmacokinetic review suggested the need for higher doses for attaining the antiviral action, it is also extremely hard to administer the prescribed inhibitory concentration in humans.¹⁶⁰

Interferon α and β

Interferons (IFNs) are cytokines that respond to viral infection by stimulating the innate immune system. IFN itself is a broad-spectrum antiviral drug but has no direct action. However, IFN can induce protein synthesis with immunomodulatory and antiviral effects. IFN could also improve the unique cytotoxic effect of the host cell immune cells.¹⁶⁰ Moreover, the first vital line of defense against viruses is the interferon (IFN) reaction. Recognition of the innate immune sensing stimulates type I and type III IFN response to viral infections.¹⁶¹ PEGylated and recombinant IFN- α and IFN- β have already been used in the treatment of numerous diseases, including viral hepatitis and multiple sclerosis (MS). Thus, global concern has been revealed for the propositioning of INF against the current COVID-19.^{153,162} Hence, to incorporate therapeutic rational methods and determine their clinical effectiveness in COVID-19, the biology of coronavirus infections should be closely studied.¹⁶³

Clinical Trials and Combination Therapy

Clinical trials have shown that IFN reaction in SARS patients is not caused by substantial IFN-I development despite the robust chemokine or cytokine development.¹⁵⁵ Serum analysis of COVID-19 patients revealed that the pro-inflammatory chemokines and cytokines were high without any observable amount of type I inflammatory chemokines and cytokines, however, no significant amounts were found. Other experiments showed that the effect of IFN on the virus can be postponed instead of its full absence by studying SARS-CoV-infected cells' transcriptome over time. Also, it was revealed that IFNs can delay the pro-inflammatory cytokines.¹⁶⁴

Moreover, interferon combination with ribavirin caused adverse effects in a systematic review of 8 kinds of research (116 patients) of MERS-CoV interferon treatment: one patient had apparent hemolysis, and two patients had an elevation in the pancreatic enzymes.¹⁶⁵

Chlorpromazine

Chlorpromazine (CPZ), a phenothiazine derivative, was selected for Largactil as a French commercial name because it has a wide variety of properties: antiemetic, antiviral, anxiolytic, antifungal properties, immunomodulatory impact, clathrin-mediated endocytosis inhibition, blood-brain barrier modulating function, etc. It acts by inhibiting the assembly of the modulator on cell surfaces and endosomes by CPZ-HCl and thereby prevents the entry of the virus into host cells. Besides, chlorpromazine is used to treat psychotic disorders such as manic-depression or schizophrenia and also treats vomiting, nausea, anxiety, symptoms of tetanus, acute intermittent porphyria, and chronic hiccups.¹⁰⁰

Clinical Trials

The CPZ displayed anti-MERS-CoV and anti-SARS-CoV-1 activity, as noted in recent in vitro studies. It is believed that CPZ may reduce COVID-19 infection in patients who require respiratory assistance without ICU.¹⁰⁰

Emetine

Emetine is an inhibitor of protein synthesis used in the treatment of amebiasis as an anti-protozoan; it can also prevent malaria by binding the *Plasmodium falciparum* ribosomal E site. Its possible cardiotoxicity in recent years has limited its therapeutic application. Its antiviral effects were tested against a wide variety of RNA and DNA viruses including Ebola virus, Zika virus, HIV-1, Cytomegalovirus, Poxvirus buffalo, Echovirus-1, Plague of the tiny ruminants virus, Herpesvirus bovine 1, Newcastle virus, Metapneumovirus, Herpes simplex virus-2, Fever virus of the Rift River, and influenza viruses.¹⁶⁶

Clinical Trials and Combination Therapy

Emetine was also reported to inhibit SARS-CoV, MERS-CoV, and MHV-A59 in vitro. It was found to inhibit SARS-CoV-2 replication at 0.5 μM efficiently. Its therapeutic plasma levels for SARS-CoV-2 can exceed 0.075 $\mu\text{g/mL}$ below EC_{50} in vitro. The poisonous concentration in the plasma is 0.5 $\mu\text{g/mL}$.¹⁰⁰ Remdesivir at 6.25 μM may hit 64.9% of viral production inhibition in combination with emetine at 0.195 μM and should be further evaluated in vivo.¹⁰⁰

Aplidin

In March 2020, it was announced that aplidin has antiviral activity. It is widely used in the treatment of multiple myeloma.¹⁶⁷

Clinical Trials

In-vitro studies have shown that aplidin affects Elongation Factor 1 Alpha (EF1A), the key to the multiplication and spread of the virus. The antiviral effect of aplidin was first studied in HCoV-229E-GFP like virus and human hepatoma cell line. Concerning SARS-CoV-2, the preliminary findings are pretty good. Furthermore, a randomized multi-center proof of the concept-clinical research is pending.¹⁶⁷

Teicoplanin

It is a glycopeptide antibiotic that is commonly used for the treatment of bacterial infections. Besides, it is actively used against SARS-CoV and is included in the prescription list for COVID-19 treatment. Teicoplanin can treat the infections of gram-positive bacteria, especially streptococcal and staphylococcal infections, and is also widely employed for treating viruses like HIV, Influenza virus, Hepatitis C virus, Flavivirus, Ebola, and Coronaviruses like SARS-CoV, and MERS-CoV.¹⁶⁸

Teicoplanin works at the early viral replication stages, preventing the release of the viral genome and the viral replication cycle by low-pH cleavage of the viral spike protein with cathepsin L at the late endosomes (Cathepsin L calls for the incorporation of the 2019-nCoV virus into the cell, and its main target region is the S protein).¹⁶⁹

Clinical Trials

Junsong Zhang found that the cleavage site cathepsin L has been maintained among SARS-CoV and 2019-nCoV S protein. In vitro, the required IC_{50} of teicoplanin concentration is 1.66 μM , which is far below the human blood level of 8.78 μM for a 400 mg daily dosage.¹¹³

Baricitinib

Baricitinib has a high binding ability for the Janus kinase (JAK) inhibitor through which it binds and inhibits Adaptor Associated Protein Kinase 1 (AAK1). Therefore, both viral penetration and inflammatory reaction associated with SARS-CoV-2 infection may be impaired by its use. JAK inhibitors for cancer and inflammatory disorders like rheumatoid arthritis are employed.¹⁷⁰ JAK inhibitors like fedratinib and ruxolitinib, which are closely related to baricitinib, increase the level of clathrin-mediated endocytosis and thus may not be effective in reducing the viral infectivity at tolerable

levels. Its medicinal use is associated with neutropenia, lymphocytopenia, and viral reactivation.⁴⁹ New evidence of the antiviral Remdesivir and the immunomodulatory Baricitinib's good therapeutic activity against COVID-19 has recently emerged.¹⁷¹

Clinical Trials

Baricitinib is expected to treat the cytokine storm triggered by COVID-19 by suppressing JAK1/JAK2. There have been a variety of clinical trials all over the world, one of which has revealed promising outcomes in which baricitinib (2–4 mg) was prescribed for 1–2 weeks uniformly. However, Deep Vein Thrombosis and Pulmonary Embolism (DVT/PE), excessive liver enzymes, and irregular blood routine were typical and significant adverse reactions. In patients with the aforementioned risk factors, baricitinib should be used with caution. Human data are not adequate for its use in pregnant women. Thus, discontinuation or dose modification should be cautiously considered when using it in patients with renal insufficiency.¹⁷²

Rapamycin

The repositioning of rapamycin has been a long history. It was first used as an antifungal and eventually as an immunosuppressive agent for organ transplant patients.¹⁷³ It triggers the downstream interruption of the signal transduction pathway to mTOR phosphorylation (mTORC1). Inhibition of mTOR counteracts viral duplication and improves the outcomes of cases that have some viral infections, such as H1N1 pneumonia,¹⁷⁴ MERS-CoV,¹⁷⁵ Andes virus,¹⁷⁶ and HCV.¹⁷⁷

Lianhuaqingwen Capsule

Lianhuaqingwen (LH) is used specifically for the treatment of influenza. It suppresses symptoms like hyperpyrexia or fever, nasal obstruction, muscle soreness, running nose, aversion to cold, headache, and cough. So, adults are advised to take four capsules 3 times daily.⁹⁰

Clinical Trials

Chinese doctors used LH for the treatment of cases with common and severe COVID-19. LH has shown good anti-inflammatory and antiviral activities against novel coronaviruses in vitro as a potential agent for the treatment of SARS-CoV-2.¹⁷⁸ Thus, a separate randomized controlled trial (RCT) has demonstrated that antiviral treatment with LH can greatly improve the symptoms during COVID-19, such as cough, fever, and tiredness in most cases. It may also alleviate symptoms of pneumonia and shorten pneumonia symptoms considerably without any significant adverse effects detected.¹⁷⁹ Furthermore, the antiviral effectiveness of LH and other traditional Chinese medications during a pandemic also played a reliable role in SARs-CoV-2 treatment.⁹⁰

Convalescent Plasma

COVID-19 convalescent plasma, also known as “survivor’s plasma,” is blood plasma derived from patients who have recovered from COVID-19. Recently, the FDA issued an Emergency Use Authorization to allow its use in hospitalized patients with COVID-19.¹⁸⁰ This technique shows that the plasma or clean monoclonal antibodies developed against COVID-19 may be taken from fully recovered patients and then delivered as a treatment to new patients.¹⁸¹

Clinical Trials

In a new study, 5 seriously ill COVID-19 cases were treated with convalescent plasma from 20 January to 25 March 2020 in China, Shenzhen.¹⁸² At this trial, patients gained the specific antibody of SARS-CoV-2 from 10 to 22 days posts the treatment by convalescent plasma. Four of the five cases experienced reduced virus loads and better outcomes in sequential organ dysfunction. In the last 12 days post the transfusion, their viral test was still negative. The four patients were all removed from artificial ventilation after 2 weeks of admission. But, in nearly 50 days, three patients were eventually released from the hospital.¹⁸³ Although the sample size of this trial is incredibly limited, the effects of convalescent plasma therapy are encouraging. Hence, this method of care is suggested in the US.¹⁸¹

Table 2 Some Recently Synthesized Compounds for COVID-19 Treatment Including Their Mode of Action and Chemical Structure

Drug	MOA	Uses	Chemical Structure
Molnupiravir ^{184–186}	By copying errors during SARS-CoV-2 RNA replication	COVID-19 treatment	
PF-07321332 ^{187–189}	An inhibitor of SARS-CoV-2 main protease	COVID-19 treatment	

Some Recently Synthesized Compounds and Approved for COVID-19 Treatment (Table 2)

Molnupiravir

Recently, molnupiravir is a prodrug antiviral medication that was approved in the United Kingdom in November 2021. It is a synthetic nucleoside derivative and works by inhibiting certain RNA viruses through copying errors during RNA replication. Thereby, molnupiravir is used to treat COVID-19 as depicted in Table 2.^{184–186}

Pf-07321332

PF-07321332 is an oral antiviral drug developed by Pfizer. It works as an active main protease inhibitor as depicted in Table 2. For the treatment of COVID-19, the PF-07321332/ritonavir combination medication is in phase III studies and will be marketed as Paxlovid.^{187–189} Ritonavir slows the metabolism of PF-07321332 by cytochrome enzymes in this combination, maintaining higher circulating concentrations of the main drug.

Clinical Trials

Pfizer published Phase 2/3 data in November 2021, which included an 89% decrease in hospitalizations when given within three days of symptom onset.^{190,191}

Conclusions

This article shows an overview that summarizes the efficacy of diverse drugs, classified according to their mechanism of action, against the SARS-CoV-2. In this review, antiviral drugs including fusion inhibitors, protease inhibitors, neuraminidase inhibitors, M2 ion-channel protein blockers, and other non-antiviral drugs that might have activities against SARS-CoV-2 were thoroughly discussed. Besides, the newly FDA-approved molnupiravir and PF-07321332 were discussed shedding light on their mechanism of action and eligibility as novel oral pills combating SARS-CoV-2 by decreasing hospitalizations for COVID-19 patients.

Drug Design, Development and Therapy

Dovepress

Publish your work in this journal

Drug Design, Development and Therapy is an international, peer-reviewed open-access journal that spans the spectrum of drug design and development through to clinical applications. Clinical outcomes, patient safety, and programs for the development and effective, safe, and sustained use of medicines are a feature of the journal, which has also been accepted for indexing on PubMed Central. The manuscript management system is completely online and includes a very quick and fair peer-review system, which is all easy to use. Visit <http://www.dovepress.com/testimonials.php> to read real quotes from published authors.
